Introduction

▶ Main idea:
Estimate properties of estimators (such as the variance, distribution, confidence intervals) by resampling the original data.

▶ Key paper: Efron (1979)
Slightly expanded version of the key idea

► Classical Setup in Statistics:

\[ X \sim F, \quad F \in \Theta \]

where \( X \) is the random object containing the entire observation. (often, \( \Theta = \{ F_a; a \in A \} \) with \( A \subset \mathbb{R}^d \)).

► Tests, CIs, . . . are often built on a real-valued test statistics \( T = T(X) \).

► Need distributional properties of \( T \) for the “true” \( F \) (or for \( F \) under \( H_0 \)) to do tests, construct CIs,. . . (e.g. quantiles, sd, . . .).

► Classical approach: construct \( T \) to be an (asymptotic) pivotal quantity, with distribution not depending on the unknown parameter. This is often not possible or requires lengthy asymptotic analysis.

► Key idea of bootstrap: Replace \( F \) by (some) estimate \( \hat{F} \), get distributional properties of \( T \) based on \( \hat{F} \).
Mouse Data

(Efron & Tibshirani, 1993, Ch. 2)

- 16 mice randomly assigned to treatment or control
- Survival time in days following a test surgery

<table>
<thead>
<tr>
<th>Group</th>
<th>Data</th>
<th>Mean (SD)</th>
<th>Median (SD)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Treatment</td>
<td>94 197 16 38 99 141 23</td>
<td>86.86 (25.24)</td>
<td>94 (?)</td>
</tr>
<tr>
<td>Control</td>
<td>52 104 146 10 51 30 40 27 46</td>
<td>56.22 (14.14)</td>
<td>46 (?)</td>
</tr>
</tbody>
</table>

Difference: 30.63 (28.93) 48 (?)

- Did treatment increase survival time?
- A good estimator of the the standard deviation of the mean
  \( \bar{x} = \frac{1}{n} \sum_{i=1}^{n} x_i \) is the sample error
  \[
  \hat{s} = \sqrt{\frac{1}{n(n-1)} \sum_{i=1}^{n} (x_i - \bar{x})^2}
  \]

- What estimator to use for the SD of the median?
- What estimator to use for the SD of other statistics?
Bootstrap Principle

- test statistic $T(x)$, interested in $SD(T(X))$
- Resampling with replacement from $x_1, \ldots, x_n$ gives a bootstrap sample $x^* = (x_1^*, \ldots, x_n^*)$ and a bootstrap replicate $T(x^*)$.
- get $B$ independent bootstrap replicates $T(x^*_1), \ldots, T(x^*_B)$
- estimate $SD(T(X))$ by the empirical standard deviation of $T(x^*_1), \ldots, T(x^*_B)$
Back to the Mouse Example

- $B=10000$

Bootstrap World

Estimated Probability Model $\hat{P}$ → $x^* = (x_1^*, \ldots, x_n^*)$

Bootstrap Sample $T(x^*)$

Bootstrap Replication
Sources of Variability

- sampling variability (we only have a sample of size $n$)
- bootstrap resampling variability (only $B$ bootstrap samples)

![Diagram showing sources of variability: sampling variability and bootstrap resampling variability.](image)
Parametric Bootstrap

- Suppose we have a parametric model $P_\theta$, $\theta \in \Theta \subset \mathbb{R}^d$.
- $\hat{\theta}$ estimator of $\theta$
- Resample from the estimated model $P_{\hat{\theta}}$. 
Example: Problems with (the Nonparametric) Bootstrap

- \(X_1, \ldots, X_{50} \sim U(0, \theta)\) iid, \(\theta > 0\)
- MLE \(\hat{\theta} = \max(X_1, \ldots, X_{50}) = 0.989\)
- Non-parametric Bootstrap: \(X_1^*, \ldots, X_{50}^*\) sampled indep. from \(X_1, \ldots, X_{50}\) with replacement.
- Parametric Bootstrap: \(X_1^*, \ldots, X_{50}^* \sim U(0, \hat{\theta})\)
- Resulting CDF of \(\hat{\theta}^* = \max(X_1, \ldots, X_{50})\):

In the nonparametric bootstrap: Large probability mass at \(\hat{\theta}\).
In fact \(P(\hat{\theta}^* = \hat{\theta}) = 1 - (1 - 1/n)^n \xrightarrow{n \to \infty} 1 - e^{-1} \approx .632\)

Further Topics
Plug-in Principle I

Many quantities of interest can be written as a functional $T$ of the underlying probability measure $P$, e.g. the mean can be written as

$$T(P) = \int xdP(x).$$

Suppose we have iid observation $X_1, \ldots, X_n$ from $P$. Based on this we get an estimated distribution $\hat{P}$ (empirical distribution or parametric distribution with estimated parameter).

We can use $T(\hat{P})$ as an estimator of $T(P)$. For the mean and the empirical distribution $\hat{P}$ of the observations $X_i$ this is just the sample mean:

$$T(\hat{P}) = \int xd\hat{P}(x) = \frac{1}{n} \sum_{i=1}^{n} X_i.$$
Plug-in Principle II

- To determine the variance of the estimator $T(\hat{P})$, compute confidence intervals for $T(P)$, or conduct tests we need the distribution of $T(\hat{P}) - T(P)$.

- Bootstrap sample: sample $X_1^*, \ldots, X_n^*$ from $\hat{P}$; gives new estimated distribution $P^*$.

- Main idea: approximate the distribution of $T(\hat{P}) - T(P)$ by the distribution of $T(P^*) - T(\hat{P})$ (which is conditional on the observed $\hat{P}$).
Bootstrap Interval

- Quantity of interest is $T(P)$
- To construct a one-sided $1 - \alpha$ CI we would need $c$ s.t. $P(T(\hat{P}) - T(P) \geq c) = 1 - \alpha$.
  Then a $1 - \alpha$ CI would be $(-\infty, T(\hat{P}) - c)$.
  Of course, $P$ and thus $c$ are unknown.
- Instead of $c$ use $c^*$ given by
  $$\hat{P}(T(P^*) - T(\hat{P}) \geq c^*) = 1 - \alpha$$
  This gives the (approximate) confidence interval
  $$(-\infty, T(\hat{P}) - c^*)$$
- Similarly for two-sided confidence intervals.
Studentized Bootstrap Interval

- Improve coverage probability by studentising the estimate.
- Quantity of interest $T(P)$, measure of standard deviation $\sigma(P)$
- Base confidence interval on $\frac{T(\hat{P}) - T(P)}{\sigma(\hat{P})}$
- Use quantiles from $\frac{T(P^*) - T(\hat{P})}{\sigma(P^*)}$. 
Efron’s Percentile Method

- Use quantiles from $T(P^*)$
- (less theoretical backing)
- Agrees with simple bootstrap interval for symmetric resampling distributions, but does not work well with skewed distributions.
Example - CI for Mean of Exponential Distribution I

- $X_1, \ldots, X_n \sim \text{Exp}(\theta)$ iid
- Confidence interval for $E X_1 = \frac{1}{\theta}$.
- Nominal level 0.95
- One-sided confidence intervals:
  
  Coverage probabilities:

<table>
<thead>
<tr>
<th></th>
<th>10</th>
<th>20</th>
<th>40</th>
<th>80</th>
<th>160</th>
<th>320</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normal Approximation</td>
<td>0.845</td>
<td>0.883</td>

<td>0.922</td>
<td>0.942</td>
<td>0.949</td>
<td>0.946</td>
<td>0.944</td>
</tr>
</tbody>
</table>

- 100000 replications for the normal CI, bootstrap CIs based on 2000 replications with 500 bootstrap samples each
- Substantial coverage error for small $n$
- Coverage error ↘ as $n$ ↗
- Studentized Bootstrap seems to be doing best.
Example - CI for Mean of Exponential Distribution II

- Two-sided confidence intervals

Coverage probabilities:

<table>
<thead>
<tr>

Dependent Data

Further Topics
Hypothesis Testing through Bootstrapping

- Setup: $H_0 : \theta \in \Theta_0$ v.s. $H_1 : \theta \notin \Theta_0$
- Observed sample: $x$
- Suppose we have a test with a test statistic $T = T(X)$ that rejects for large values
- p-value, in general: $p = \sup_{\theta \in \Theta_0} P_{\theta}(T(X) \geq T(x))$
  If we know that only $\theta_0$ might be true: $p = P_{\theta_0}(T(X) \geq T(x))$
- Using the sample, find estimator $\hat{P}_0$ of the distr. of $X$ under $H_0$
- Generate iid $X^*1, \ldots, X^*B$ from $\hat{P}_0$
- Approximate the p-value via
  $$\hat{p} = \frac{1}{B} \sum_{i=1}^{B} \mathbb{I}(T(X^*i) \geq T(x))$$
- To improve finite sample performance, it has been suggested to use
  $$\hat{p} = \frac{1 + \sum_{i=1}^{B} \mathbb{I}(T(X^*i) \geq T(x))}{B + 1}$$
Example - Two Sample Problem - Mouse Data

- Two Samples: treatment $y$ and control $z$ with cdfs $F$ and $G$
- $H_0 : F = G$, $H_1 : G \leq_{st} F$
- $T(x) = T(y, z) = \bar{y} - \bar{z}$, reject for large values
- Pooled sample: $x = (y', z')$.
- Bootstrap sample $x^* = (y^*, z^*)$: sample from $x$ with replacement
- p-value: generate independent bootstrap samples $x^*1, \ldots, x^*B$

$$
\hat{p} = \frac{1}{B} \sum_{i=1}^{B} I\{T(x^*i) \geq T(x)\}
$$

- Mouse Data: $t_{obs} = 30.63 \ B = 2000 \ \hat{p} = 0.134$
How to Choose the Number of Resamples (i.e. B)?

(Davison & Hinkley, 1997, Section 4.25)

- Not using the ideal bootstrap based on infinite number of resamples leads to a loss of power!
- Indeed, if $\pi_\infty(u)$ is the power of a fixed alternative for a test of level $u$ then it turns out that the power $\pi_B(u)$ of a test based on $B$ bootstrap resamples is

$$
\pi_B(u) = \int_0^1 \pi_\infty(u) f_{(B+1)\alpha,(B+1)(1-\alpha)}(u) \, du
$$

where $f_{(B+1)\alpha,(B+1)(1-\alpha)}(u)$ is the Beta-density with parameters $(B + 1)\alpha$ and $(B + 1)(1 - \alpha)$. 
If one assumes that $\pi_B(u)$ is concave, then one can obtain the approximate bound

$$\frac{\pi_B(\alpha)}{\pi_\infty(\alpha)} \geq 1 - \sqrt{\frac{1 - \alpha}{2\pi(B + 1)\alpha}}$$

A table of those bounds:

<table>
<thead>
<tr>
<th>$B$=</th>
<th>19</th>
<th>39</th>
<th>99</th>
<th>199</th>
<th>499</th>
<th>999</th>
<th>9999</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\alpha = 0.01$</td>
<td>0.11</td>
<td>0.37</td>
<td>0.6</td>
<td>0.72</td>
<td>0.82</td>
<td>0.87</td>
<td>0.96</td>
</tr>
<tr>
<td>$\alpha = 0.05$</td>
<td>0.61</td>
<td>0.73</td>
<td>0.83</td>
<td>0.88</td>
<td>0.92</td>
<td>0.95</td>
<td>0.98</td>
</tr>
</tbody>
</table>

(These bounds may be conservative)

To be safe: use at least $B = 999$ for $\alpha = 0.05$ and even a higher $B$ for smaller $\alpha$. 

(These bounds may be conservative)
Sequential Approaches

- General Idea: Instead of a fixed number of resamples $B$, allow the number of resamples to be random.
- Can e.g. stop sampling once test decision is (almost) clear.
- Potential advantages:
  - Save computer time.
  - Get a decision with a bounded resampling error.
  - May avoid loss of power.
Saving Computational Time

- It is not necessary to estimate high values of the p-value \( p \) precisely.
- Stop if \( S_n = \sum_{i=1}^{n} I(T(X^*i) \geq T(x)) \) “large”.
- Besag & Clifford (1991):
  Stop after \( \tau = \min\{n : S_n \geq h\} \land m \) steps

\[
\hat{p} = \begin{cases} 
\frac{h}{\tau} & S_\tau = h \\
\frac{(S_\tau + 1)}{m} & \text{else}
\end{cases}
\]
Uniform Bound on the Resampling Risk

The boundaries below are constructed to give a uniform bound on the resampling risk: ie for some (small) $\epsilon > 0$,

$$\sup_P P_p(\text{wrong decision}) \leq \epsilon$$

Details, see Gandy (2009).
Other issues

- How to compute the power/level (rejection probability) of Bootstrap tests?
  See (Gandy & Rubin-Delanchy, 2013) and references therein.

- How to use bootstrap tests in multiple testing corrections (eg FDR)?
  See (Gandy & Hahn, 2012) and references therein.
Outline

Introduction

Confidence Intervals

Hypothesis Tests

Asymptotic Properties
  Main Idea
  Asymptotic Properties of the Mean

Higher Order Theory

Iterated Bootstrap

Dependent Data

Further Topics
Main Idea

- Asymptotic theory does not take the resampling error into account - it assumes the 'ideal' bootstrap with an infinite number of replications.
- Observations $X_1, X_2, \ldots$
- Often:
  $$
  \sqrt{n}(T(\hat{P}) - T(P)) \xrightarrow{d} F
  $$
  for some distribution $F$.
- Main asymptotic justification of the bootstrap: Conditional on the observed $X_1, X_2, \ldots$:
  $$
  \sqrt{n}(T(P^*) - T(\hat{P})) \xrightarrow{d} F
  $$
Conditional central limit theorem for the mean

- Let $X_1, X_2, \ldots$ be iid random vectors with mean $\mu$ and covariance matrix $\Sigma$.
- For every $n$, suppose that $\bar{X}_n^* = \frac{1}{n} \sum_{i=1}^{n} X_i^*$, where $X_i^*$ are samples from $X_1, \ldots, X_n$ with replacement.
- Then conditionally on $X_1, X_2, \ldots$ for almost every sequence $X_1, X_2, \ldots$,

$$\sqrt{n}(\bar{X}_n^* - \bar{X}_n) \xrightarrow{d} N(0, \Sigma) \quad (n \to \infty).$$

- Proof:
  Mean and Covariance of $\bar{X}_n^*$ are easy to compute in terms of $X_1, \ldots, X_n$.
  Use central limit theorem for triangular arrays (Lindeberg central limit theorem).
Delta Method

- Can be used to derive convergence results for derived statistics, in our case functions of the sample mean.

- Delta method: If \( \phi \) is continuously differentiable,
  \[
  \sqrt{n}(\hat{\theta}_n - \theta) \xrightarrow{d} T \quad \text{and} \quad \sqrt{n}(\hat{\theta}^*_n - \hat{\theta}) \xrightarrow{d} T \quad \text{conditionally then}
  \sqrt{n}(\phi(\hat{\theta}_n) - \phi(\theta)) \xrightarrow{d} \phi'(T) \quad \text{and} \quad \sqrt{n}(\phi(\hat{\theta}^*_n) - \phi(\hat{\theta})) \xrightarrow{d} \phi'(T) \quad \text{conditionally.}
  \]

Example

Suppose \( \theta = \begin{pmatrix} \text{E}(X) \\ \text{E}(X^2) \end{pmatrix} \) and \( \hat{\theta}_n = \begin{pmatrix} \frac{1}{n} \sum_{i=1}^{n} X_i \\ \frac{1}{n} \sum_{i=1}^{n} X_i^2 \end{pmatrix} \). Then convergence of \( \sqrt{n}(\hat{\theta} - \theta) \) can be established via CLT.

Using \( \phi(\mu, \eta) = \eta - \mu^2 \) gives a limiting result for estimates of variance.
Bootstrap and Empirical Process theory

- Flexible and elegant theory based on expectations wrt the empirical distribution

\[ P_n = \frac{1}{n} \sum_{i=1}^{n} \delta_{X_i} \]

(many test statistics can be constructed from this)

- Gives uniform CLTs/LLN: Donkser theorems/Glivenko-Cantelli theorems

- Can be used to derive asymptotic results for the bootstrap (e.g. for bootstrapping the sample median); use the bootstrap empirical distribution

\[ P_n^* = \frac{1}{n} \sum_{i=1}^{n} \delta_{X_i^*}. \]

- For details see van der Vaart (1998, Section 23.1) and van der Vaart & Wellner (1996, Section 3.6).
Outline

Introduction

Confidence Intervals

Hypothesis Tests

Asymptotic Properties

**Higher Order Theory**

   Edgeworth Expansion
   Higher Order of Convergence of the Bootstrap

Iterated Bootstrap

Dependent Data

Further Topics
Introduction

- It can be shown that the bootstrap has a faster convergence rate than simple normal approximations.
- Main tool: Edgeworth Expansion - refinement of the central limit theorem
- Main aim of this section: to explain the Edgeworth expansion and then mention briefly how it gives the convergence rates for the bootstrap.
- (reminder: this is still not taking the resampling risk into account, i.e. we still assume $B = \infty$)
- For details see Hall (1992).
Edgeworth Expansion

- $\theta_0$ unknown parameter
- $\hat{\theta}_n$ estimator based on sample of size $n$
- Often,
  \[
  \sqrt{n}(\hat{\theta}_n - \theta) \xrightarrow{d} N(0, \sigma^2) \quad (n \to \infty),
  \]
i.e. for all $x$,
  \[
P(\sqrt{n} \frac{\hat{\theta}_n - \theta}{\sigma} \leq x) \to \Phi(x) \quad n \to \infty,
  \]
where $\Phi(x) = \int_{-\infty}^{x} \phi(t)dt$, $\phi(t) = \frac{1}{\sqrt{2\pi}} e^{-t^2/2}$.
- Often one can write this as power series in $n^{-\frac{1}{2}}$:
  \[
P(\sqrt{n} \frac{\hat{\theta}_n - \theta}{\sigma} \leq x) = \Phi(x) + n^{-\frac{1}{2}} p_1(x)\phi(x) + \cdots + n^{-\frac{j}{2}} p_j(x)\phi(x) + \ldots
  \]
This expansion is called Edgeworth Expansion.
- Note: $p_j$ is usually an even/odd function for odd/even $j$.
- Edgeworth Expansion exist in the sense that for a fixed number of approximating terms, the remainder term is of lower order than the last included term.
Edgeworth Expansion - Arithmetic Mean I

Suppose we have a sample $X_1, \ldots, X_n$, and

$$\hat{\theta}_n = \frac{1}{n} \sum_{i=1}^{n} X_i.$$ 

Then

- $p_1(x) = -\frac{1}{6} \kappa_3 (x^2 - 1)$
- $p_2(x) = -x \left( \frac{1}{24} \kappa_4 (x^2 - 3) + \frac{1}{72} \kappa_3^2 (x^4 - 10x^2 + 15) \right)$

where $\kappa_j$ are the cumulants of $X$, in particular

- $\kappa_3 = E(X - E X)^3$ is the skewness
- $\kappa_4 = E(X - E X)^4 - 3(\text{Var} X)^2$ is the kurtosis.

(In general, the $j$th cumulant $\kappa_j$ of $X$ is the coefficient of $\frac{1}{j!} (it)^j$ in a power series expansion of the logarithm of the characteristic function of $X$.)
Edgeworth Expansion - Arithmetic Mean II

- The Edgeworth expansion exists if the following is satisfied:
  - Cramér's condition: \( \lim_{|t| \to \infty} |E \exp(itX)| < 1 \) (satisfied if the observations are not discrete, i.e. possess a density wrt Lebesgue measure).
  - A sufficient number of moments of the observations must exist.
Edgeworth Expansion - Arithmetic Mean - Example

$X_i \sim \text{Exp}(1) \ iid$, $\hat{\theta} = \frac{1}{n} \sum_{i=1}^{n} X_i$

The Edgeworth Expansion provides an improvement to the approximate distribution of the sample mean, especially when the sample size is not large. The expansion is given by:

$$
\Phi(x) + \frac{1}{n^{1/2}} p_1(x) \phi(x) + \frac{1}{n} p_2(x) \phi(x)
$$

where $\Phi(x)$ is the true distribution function, $\phi(x)$ is the standard normal density function, and $p_1(x)$ and $p_2(x)$ are the first and second order correction terms, respectively.
Coverage Prob. of CIs based on Asymptotic Normality I

Suppose we construct a confidence interval based on the standard normal approximation to

\[ S_n = \sqrt{n}(\hat{\theta}_n - \theta_0)/\sigma \]

where \( \sigma \) is the asymptotic variance of \( \sqrt{n}\hat{\theta}_n \).

One-sided nominal \( \alpha \)-level confidence intervals:

\[ I_1 = (-\infty, \hat{\theta} + n^{-1/2}\sigma z_\alpha) \]

where \( z_\alpha \) is defined by \( \Phi(z_\alpha) = \alpha \).

\[
\begin{align*}
P(\theta_0 \in I_1) &= P(\theta_0 < \hat{\theta} + n^{-1/2}\sigma z_\alpha) = P(S_n > -z_\alpha) \\
&= 1 - (\Phi(-z_\alpha) + n^{-1/2}p_1(-z_\alpha)\phi(-z_\alpha) + O(n^{-1})) \\
&= \alpha - n^{-1/2}p_1(z_\alpha)\phi(z_\alpha) + O(n^{-1}) \\
&= \alpha + O(n^{-1/2})
\end{align*}
\]
Two-sided nominal $\alpha$-level confidence intervals:

$$l_2 = \left( \hat{\theta} - n^{-1/2} \sigma x_\alpha, \hat{\theta} + n^{-1/2} \sigma x_\alpha \right)$$

where $x_\alpha = z_{(1+\alpha)/2}$,

$$P(\theta_0 \in l_2) = P(S_n \leq x_\alpha) - P(S_n \leq -x_\alpha)$$

$$= \Phi(x_\alpha) - \Phi(-x_\alpha)$$

$$+ n^{-1/2} \left[ p_1(x_\alpha) \phi(x_\alpha) - p_1(-x_\alpha) \phi(-x_\alpha) \right]$$

$$+ n^{-1} \left[ p_2(x_\alpha) \phi(x_\alpha) - p_2(-x_\alpha) \phi(-x_\alpha) \right]$$

$$+ n^{-3/2} \left[ p_3(x_\alpha) \phi(x_\alpha) - p_3(-x_\alpha) \phi(-x_\alpha) \right] + O(n^{-2})$$

$$= \alpha + 2n^{-1} p_2(x_\alpha) \phi(z_\alpha) + O(n^{-2}) = \alpha + O(n^{-1})$$

To summarise: Coverage error for one-sided CI: $O(n^{-1/2})$, for two-sided CI: $O(n^{-1})$. 
Higher Order Convergence of the Bootstrap I

- Will consider the studentized bootstrap first.
- Consider the following Edgeworth expansion of $\frac{\hat{\theta}_n - \theta}{\hat{\sigma}_n}$:

$$P \left( \frac{\hat{\theta}_n - \theta}{\hat{\sigma}_n} \leq x \right) = \Phi(x) + n^{-\frac{1}{2}} p_1(x) \phi(x) + O \left( \frac{1}{n} \right)$$

- The Edgeworth expansion usually remains valid in a conditional sense, i.e.

$$\hat{P} \left( \frac{\hat{\theta}_n^* - \hat{\theta}_n}{\sigma_n^*} \leq x \right) = \Phi(x) + n^{-\frac{1}{2}} \hat{p}_1(x) \phi(x) + \ldots + n^{-\frac{i}{2}} \hat{p}_j(x) \phi(x) + \ldots$$

Use the first expansion term only, i.e.
Higher Order Convergence of the Bootstrap II

\[ \hat{P} \left( \frac{\hat{\theta}^*_n - \hat{\theta}_n}{\sigma^*_n} \leq x \right) = \Phi(x) + n^{-\frac{1}{2}} \hat{p}_1(x) \phi(x) + O \left( \frac{1}{n} \right) \]

Usually \( \hat{p}_1(x) - p_1(x) = O \left( \frac{1}{\sqrt{n}} \right) \).

Then

\[ P \left( \frac{\hat{\theta}_n - \theta}{\hat{\sigma}_n} \leq x \right) - \hat{P} \left( \frac{\hat{\theta}^*_n - \hat{\theta}_n}{\sigma^*_n} \leq x \right) = O \left( \frac{1}{n} \right) \]

Thus the studentized bootstrap results in a better rate of convergence than the normal approximation (which is \( O(1/\sqrt{n}) \) only).

For a non-studentized bootstrap the rate of convergence is only \( O(1/\sqrt{n}) \).
Higher Order Convergence of the Bootstrap III

- This translates to improvements in the coverage probability of (one-sided) confidence intervals. The precise derivations of these also involve the so-called Cornish-Fisher expansions, an expansion of quantile functions similar to the Edgeworth expansion (which concerns distribution functions).

Introduction

- Iterate the Bootstrap to improve the statistical performance of bootstrap tests, confidence intervals,...
- If chosen correctly, the iterated bootstrap can have a higher rate of convergence than the non-iterated bootstrap.
- Can be computationally intensive.
- Some references: Davison & Hinkley (1997, Section 3.9), Hall (1992, Section 1.4, 3.11)
Double Bootstrap Test
(based on Davison & Hinkley, 1997, Section 4.5)

- Ideally the $p$-value under the null distribution should be a realisation of $U(0, 1)$.
- However, computing $p$-values via the bootstrap does not guarantee this
  (measures such as studentising the test statistics may help - but there is no guarantee)
- Idea: use an iterated version of the bootstrap to correct the $p$-value.
- let $p$ be the $p$-valued based on $\hat{P}$.
- observed - data $\rightarrow$ fitted model $\hat{P}$;
- Let $p^*$ be the random variable obtained by resampling from $\hat{P}$.
- $p_{adj} = P^*(p^* \leq p|\hat{P})$
Implementation of a Double Bootstrap Test

Suppose we have a test that rejects for large values of a test statistic.
Algorithm: For \( r = 1, \ldots, R \):

- Generate \( X_1^*, \ldots, X_n^* \) from the fitted null distribution \( \hat{P} \), calculate the test statistic \( t_r^* \) from it.
- Fit the null distribution to \( X_1^*, \ldots, X_n^* \) obtaining \( \hat{P}_r \).
- For \( m = 1, \ldots, M \):
  - generate \( X_1^{**}, \ldots, X_n^{**} \) from \( \hat{P}_r \).
  - calculate the test statistic \( t_{rm}^{**} \) from them.
- Let \( p_r^* = \frac{1 + \# \{ t_{rm}^{**} \geq t_r^* \}}{1 + M} \).

Let \( p_{adj} = \frac{1 + \# \{ p_r^* \leq p \}}{1 + M} \).

Effort: \( MR \) simulations.

\( M \) can be chosen smaller than \( R \), e.g. \( M = 99 \) or \( M = 249 \).

Iterated Bootstrap

Dependent Data
  Introduction
  Block Bootstrap Schemes
  Remarks

Further Topics
Dependent Data

- Often observations are not independent
- Example: time series
- → Bootstrap needs to be adjusted
- Main source for this chapter: Lahiri (2003).
Dependent Data - Example 1

(Lahiri, 2003, Example 1.1, p. 7)

- $X_1, \ldots, X_n$ generated by a stationary ARMA(1,1) process:

$$X_i = \beta X_{i-1} + \epsilon_i + \alpha \epsilon_{i-1}$$

where $|\alpha| < 1$, $|\beta| < 1$, $(\epsilon_i)$ is white noise, i.e. $E \epsilon_i = 0$, $\text{Var} \epsilon_i = 1$.

- Realisation of length $n = 256$ with $\alpha = 0.2$, $\beta = 0.3$, $\epsilon_i \sim N(0, 1)$:
Dependent Data - Example II

- Interested in variance of $\bar{X}_n = \frac{1}{n} \sum_{i=1}^{n} X_i$.
- Use the Nonoverlapping Block Bootstrap (NBB); Blocks of length $l$:
  1. $B_1 = (X_1, \ldots, X_l)$
  2. $B_2 = (X_{l+1}, \ldots, X_{2l})$
  3. \ldots
  4. $B_{n/l} = (X_{n-l+1}, \ldots, X_n)$
- resample blocks $B_1^*, \ldots, B_{n/l}^*$ with replacement; concatenate to get bootstrap sample
  $$(X_1^*, \ldots, X_n^*)$$
- Bootstrap estimator of variance: $\text{Var}(\frac{1}{n} \sum_{i=1}^{n} X_i^*)$
  (can be computed explicitly in this case - no resampling necessary)
## Dependent Data - Example III

- **Results for the above sample:**
  
  True Variance \( \text{Var}(\bar{X}_n) = 0.0114 \) (based on 20000 simulations)

<table>
<thead>
<tr>
<th>l</th>
<th>1</th>
<th>2</th>
<th>4</th>
<th>8</th>
<th>16</th>
<th>32</th>
<th>64</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \text{Var}(\bar{X}_n) )</td>
<td>0.0049</td>
<td>0.0063</td>
<td>0.0075</td>
<td>0.0088</td>
<td>0.0092</td>
<td>0.0013</td>
<td>0.0016</td>
</tr>
</tbody>
</table>

- **bias, standard deviation, \( \sqrt{\text{MSE}} \) based on 1000 simulations:**

<table>
<thead>
<tr>
<th>l</th>
<th>1</th>
<th>2</th>
<th>4</th>
<th>8</th>
<th>16</th>
<th>32</th>
<th>64</th>

<td>0.003</td>
<td>0.0029</td>
<td>0.0038</td>
<td>0.0055</td>
<td>0.0076</td>
</tr>
</tbody>
</table>

- **Note:**
  - Block size = 1 is the classical IID bootstrap
  - Variance increases with block size
  - Bias decreases with block size
  - Bias-Variance trade-off
Moving Block Bootstrap (MBB)

- $X_1, \ldots, X_n$ observations (realisations of a stationary process)
- $l$ block length.
- $B_i = (X_{i}, \ldots, X_{i+l-1})$ block starting at $X_i$.
- To get a bootstrap sample:
  - Draw with replacement $B_1^*, \ldots, B_k^*$ from $B_1, \ldots, B_{n-l+1}$.
  - Concatenate the blocks $B_1^*, \ldots, B_k^*$ to give the bootstrap sample $X_1^*, \ldots, X_{kl}^*$

- $l = 1$ corresponds to the classical iid bootstrap.
Nonoverlapping Block Bootstrap (NBB)

- Blocks in the MBB may overlap
- \(X_1, \ldots, X_n\) observations (realisations of a stationary process)
- \(l\) block length.
- \(b = \lfloor n/l \rfloor\) blocks:
  \[
  B_i = (X_{il+1}, \ldots, X_{il+l-1}), \quad i = 0, \ldots, b - 1
  \]
- To get a bootstrap sample: draw with replacement from these blocks and concatenate the resulting blocks.
- Note: Fewer blocks than in the MBB
Other Types of Block Bootstraps

- Generalised Block Bootstrap
  - Periodic extension of the data to avoid boundary effects
  - Reuse the sample to form an infinite sequence \((Y_k)\):
    \[
    X_1, \ldots, X_n, X_1, \ldots, X_n, X_1, \ldots, X_n, X_1, \ldots
    \]
  - A block \(B(S, J)\) is described by its start \(S\) and its length \(J\).
  - The bootstrap sample is chosen according to some probability measure on the sequences \((S_1, J_1), (S_2, J_2), \ldots\)

- Circular block bootstrap (CBB):
  - Sample with replacement from \(\{B(1, l), \ldots, B(n, l)\}\)
  - Every observation receives equal weight

- Stationary block bootstrap (SB):
  - \(S \sim \text{Uniform}(1, \ldots, n), \quad J \sim \text{Geometric}(p)\)
  - For some \(p\).
  - Blocks are no longer of equal size
Dependent Data - Remarks

- MBB and CBB outperform NBB and SB (Lahiri, 2003, see Chapter 5)
- Dependence in Time Series is a relatively simple example of dependent data
- Further examples are Spatial data or Spatio-Temporal data - here boundary effects can be far more difficult to handle.

Iterated Bootstrap

Dependent Data

Further Topics

Bagging

Boosting

Some Pointers to the Literature
Bagging I

- Acronym for *bootstrap aggregation*
- data \( d = \{ (x^{(j)}, y^{(j)}), j = 1, \ldots, n \} \)
  - response \( y \), predictor variables \( x \in \mathbb{R}^p \)
- Suppose we have a basic predictor \( m_0(x|d) \)
- Form \( R \) resampled data sets \( d^*_1, \ldots, d^*_R \).
- empirical bagged predictor:

\[
\hat{m}_B(x|d) = \frac{1}{R} \sum_{r=1}^{R} m_0(x|d^*_r)
\]

This is an approximation to

\[
m_B(x|d) = E^* \{ m_0(x|D^*) \}
\]

\( D^* \) resample from \( d \).
Bagging II

- Example: linear regression with screening of predictors (hard thresholding)

\[
m_0(x|d) = \sum_{i=1}^{p} \hat{\beta}_i \mathbb{I}(|\hat{\beta}_i| > c_i)x_i
\]

corresponding bagged estimator:

\[
m_B(x|d) = \sum_{i=1}^{p} E^*(\hat{\beta}_i \mathbb{I}(|\hat{\beta}_i| > c_i)|D^*)x_i
\]

corresponds to soft thresholding

- Bagging can improve in particular unstable classifiers (e.g. tree algorithms)
Bagging III

- For classification problems concerning class membership (i.e. a 0-1 decision is needed), bagging can work via voting (the class that the basic classifier chooses most often during resampling is reported as class)

- Key Articles: Breiman (1996a,b), Bühlmann & Yu (2002)
Boosting

- Related to Bagging
- attach weights to each observation
- iterative improvements of the base classifier by increasing the weights for those observations that are hardest to classify
- Can yield dramatic reduction in classification error.
- Key articles: Freund & Schapire (1997), Schapire et al. (1998)
Pointers to the Literature

- Efron & Tibshirani (1993) - easy to read introduction.
- Hall (1992) - Higher order asymptotics
- Lahiri (2003) - Dependent Data
- Davison & Hinkley (1997) - More applied book about the bootstrap in several situations with implementations in R.
- van der Vaart & Wellner (1996, Section 3.6): Asymptotic Theory based on empirical process theory.
