ON THE EFFECT OF COVARIANCE FUNCTION ESTIMATION ON THE ACCURACY OF KRIGING PREDICTORS

H. PUTTER AND G. A. YOUNG

UNIVERSITY OF LEIDEN AND UNIVERSITY OF CAMBRIDGE

Abstract. The kriging procedure gives an optimal linear predictor of a spatial process at a point \( x_0 \), given observations of the process at other locations \( x_1, \ldots, x_n \), taking into account the spatial dependence of the observations. The kriging predictor is optimal if the weights are calculated from the correct underlying covariance structure. In practice, this covariance structure is unknown and is estimated from the data. An important, but not very well understood, problem in kriging theory is the effect on the accuracy of the kriging predictor of substituting the optimal weights by weights derived from the estimated covariance structure. We show that the effect of estimation is negligible asymptotically if the joint Gaussian distributions of the process at \( x_0, \ldots, x_n \) under the true and the estimated covariance are contiguous almost surely. We consider a number of commonly used parametric covariance models where this can indeed be achieved.

1. Introduction

Kriging is a method for spatial prediction, widely used in mining, hydrology, forestry and other fields. Loosely speaking, given a spatial process which, observed at sampling locations \( x_1, \ldots, x_n \), gives observations \( z_1, \ldots, z_n \), it gives the optimal unbiased linear predictor of the process at a given point \( x_0 \) where the process is not observed, taking into account the

Key words and phrases. Contiguity, covariance function estimation, Gaussian process, kriging, spatial prediction, spectral density.
spatial dependence of the observations. More specifically, in its simplest form, it is assumed that a stationary Gaussian process $Z(\cdot)$ with covariance function $C(t) = \text{covar}(Z(x + t), Z(x))$ is observed at $x_1, \ldots, x_n$ and we wish to find weights $\alpha_{n1}, \ldots, \alpha_{nn}$ with $\sum_{i=1}^{n} \alpha_{ni} = 1$ such that the prediction error

$$E\left(\sum_{i=1}^{n} \alpha_{ni} Z(x_i) - Z(x_0)\right)^2$$

is minimised. The restriction on the weights ensures that the kriging predictor $\sum_{i=1}^{n} \alpha_{ni} Z(x_i)$ is unbiased, i.e. $E(\sum_{i=1}^{n} \alpha_{ni} Z(x_i) - Z(x_0)) = 0$. The kriging algorithm gives the optimal weights as a solution to a system of linear equations involving the covariances of $Z(x_1), \ldots, Z(x_n)$ (Cressie 1991, p. 123).

In order to carry out this procedure it is therefore necessary to know the underlying covariance function $C$. The theoretical kriging predictor is optimal among all unbiased linear predictors; if $Z(\cdot)$ is Gaussian among all unbiased predictors. Hence it is clear that any attempt to approximate the optimal weights while retaining unbiasedness will result in a kriging predictor that has a larger prediction error. Common practice is to estimate $C$ and adjust the weights according to the estimated covariance structure. We shall call the resulting kriging predictor the “estimating kriging predictor”. Thus, the estimating kriging prediction error is at least as great as the theoretical kriging prediction error.

Although an extremely important practical issue, the effect of estimating $C$ is still not all that well understood. There are essentially two approaches to assessing the influence of misspecifying or approximating the covariance function.

The first of these (Diamond & Armstrong 1984, Warnes 1986, Yakowitz & Szidarovsky 1985) is effectively a numerical analysis. Since the kriging weights are determined by solving linear equations involving the covariance matrix of $Z(x_1), \ldots, Z(x_n)$, approximating the covariance function results
in a perturbation of that covariance matrix. The effect of approximating
the covariance function on the kriging weights and hence on the kriging
predictor can then be expressed in terms of the condition number of the
covariance matrix. This program is carried out in detail by Diamond &
Armstrong (1984) and it gives bounds on the relative difference between
the two kriging prediction errors, which are valid for every $n$ and can be
applied for every configuration of the sampling and prediction locations.
Unfortunately, the bounds are not very sharp. In fact, as we perform more
and more measurements and acquire more observations, the bounds get
wider instead of smaller as we would expect in most situations.

In the second approach, due to Stein (1988), the true underlying covari-
ance function $C_1$ is assumed to be misspecified by a second covariance func-
tion $C_2$. The mean zero Gaussian random fields with covariance functions
$C_1$ and $C_2$, defined on a bounded region in $\mathbb{R}^d$, induce Gaussian probability
measures $\mathbb{P}_1$ and $\mathbb{P}_2$ respectively. Following Stein (1988), we call $C_1$ and $C_2$
equivalent if the induced probability laws $\mathbb{P}_1$ and $\mathbb{P}_2$ are mutually absolutely
continuous. If $C_1$ and $C_2$ are equivalent, it is shown in Stein (1988) that,
under some conditions, the effect of misspecifying $C_1$ is asymptotically negli-
gible, in the sense that the ratio of the “estimating kriging prediction error”
and the “theoretical kriging prediction error” tends to one as the number of
observations tends to infinity. Application of this result however, requires
one to keep $C_2$ fixed as the number of observations changes. What’s worse,
typically $C$ and an estimated covariance function $\hat{C}_n$ will not be equivalent
for any finite $n$.

Thus, the question remains open how approximating the true covariance
function $C$ by a sequence $C_n$ affects the accuracy of the kriging predictor.
Since Yakowitz & Szidarovsky (1985, p. 39) uttered the remark that “we
regard the situation as a (perhaps unfillable) lacuna in kriging theory”, to
the best of our knowledge the problem has not been solved to a satisfactory
degree.
The aim of this note is to study the effect of estimating the covariance function on the efficiency of kriging predictors. Our analysis is closest in nature to Stein’s approach. In fact, we mimic the proof of Theorem 1 of Stein (1988). However, where Stein passes to the limit first and considers absolute continuity of the resulting Gaussian processes, we retain the dependence on \( n \) of \( \hat{C}_n \) and the two \( n \)-dimensional Gaussian vectors defined by \( C \) and \( \hat{C}_n \) and consider contiguity of the distributions of these vectors. For a definition of contiguity and related concepts we refer to Sections 2 and 3.

We prove that, under essentially the same conditions as Stein (1988), the estimating kriging predictor is asymptotically efficient with respect to the theoretical kriging predictor, provided the \((n+1)\)-dimensional Gaussian probability distributions \( P_n \) and \( \hat{P}_n \) of \( (Z(x_0), Z(x_1), \ldots, Z(x_n)) \) under \( C \) and \( \hat{C}_n \) are contiguous almost surely.

The asymptotic setup that Stein considers is infill asymptotics, where samples are taken from a fixed bounded region and where the sampling locations become increasingly dense. This has often been opposed against increasing domain asymptotics, where the distance between neighbouring sampling locations remains bounded from below and the domain from which sampling takes place necessarily increases. Recently however, a mixture of these extremes has become popular (Hall & Patil 1994, Lahiri 1997), which combines the merits of both approaches. This mixture carries a tuning parameter that determines the degree of infilling and increasing domain and makes it a very flexible setup. Typically, this parameter is tuned in such a way that both the size of the sampling region and the number of observations in each fixed subset of that region grow with \( n \).

In principle, contiguity of \( \{P_n\} \) and \( \{\hat{P}_n\} \) will depend both on the configuration of the prediction and sampling locations and on the quality of the estimator \( \hat{C}_n \). Our result on asymptotic efficiency of the estimating kriging predictor is only useful if it is indeed possible to find an estimator \( \hat{C}_n \) of \( C \) such that \( \{P_n\} \) and \( \{\hat{P}_n\} \) are contiguous almost surely. In Section 3 we study
contiguity of Gaussian random vectors in more detail and give conditions, first on the covariance matrices involved, then on \( \hat{C}_n \) relative to \( C \) that guarantee contiguity of \( \{ P_n \} \) and \( \{ \hat{P}_n \} \). The usual way the covariance function is estimated is by using a nonparametric pilot-estimate of \( C \) and from that fit (usually by eye!) a class of commonly used parametric covariance functions (Cressie 1991, p. 61–62). The parameter of that parametric class is then estimated using standard statistical techniques like least squares, maximum likelihood and minimum norm quadratic estimation. There are a number of reasons for that. First of all, such a nonparametric pilot-estimate is notoriously ill-behaved away from the origin (Journel & Huijbregts 1978), although this may be true as well for covariance functions estimated directly within parametric classes. More importantly, this covariance function estimator may not be permissible in the sense that a covariance matrix derived from it need not be positive-definite. For a detailed account of permissibility issues see Christakos (1984). Hall & Patil (1994) propose permissible kernel-type nonparametric estimators of covariance functions. There is a slightly worrying issue concerning covariance function estimation under infill asymptotics, pointed out by Lahiri (1996). He shows that the most commonly used nonparametric estimator of \( C \) is not consistent under infill asymptotics. This makes one very suspicious about the behaviour of any estimator of \( C \) which is derived from that nonparametric covariance function estimator along the lines outlined above. It is not clear to us as yet whether (permissible) nonparametric covariance function estimators \( \hat{C}_n \) may lead to probability distributions \( P_n \) and \( \hat{P}_n \) which are contiguous almost surely. However, within a number of these parametric covariance function models, it can indeed be shown that the parameter within that model can be estimated in such a way that the corresponding Gaussian distributions are indeed contiguous almost surely. Section 4 contains a number of stylised examples that illustrate this point and connect our work with that of Stein (1988) and Stein & Handcock (1989). The examples considered here are admittedly limited in scope, with
regularly sited spatial data. We do believe that the examples in Section 4 can in fact be extended to moderately irregularly spaced spatial data as well. To prove contiguity in more general (parametric) covariance function models however, such as the Matérn model, as proposed by Stein (1999), may pose formidable problems. Finally, Section 5 discusses the estimation of the estimating kriging prediction error. We conclude this section with a number of remarks.

The fact that, within a parametric family of covariance functions \( \{C_\theta : \theta \in \Theta \subset \mathbb{R}^q\} \), the estimating kriging predictor using covariance function \( C_\theta \) is asymptotically efficient with respect to the theoretical kriging predictor using covariance function \( C_\theta \), implies that the optimal prediction error is the same, whether we know \( \theta \) or not. This phenomenon, called adaptation, is well known in parametric and semiparametric estimation (Bickel, Klaassen, Ritov & Wellner 1993, Section 2.4), but we are unaware of any previous occurrences of adaptation in the literature in the context of spatial prediction.

In the geostatistical literature the variogram

\[
2\gamma(t) = E(Z(x + t) - Z(x))^2
\]

is used more often than the covariance function, one of the reasons being that it requires a weaker assumption than the (second-order) stationarity needed for the covariance function, namely that the process has stationary increments. In case of stationarity, the relation between them is given by

\[
\gamma(t) = C(0) - C(t).
\]

Cressie (1991, p. 70) argues with some justice that variogram estimation is to be preferred to covariance function estimation. Because conditions for contiguity are most naturally expressed in terms of covariance matrices, we have preferred to state our results in terms of covariance functions rather than variograms. However, it is straightforward to translate those results to variograms as well.
As in Stein (1988), our results, formulated for ordinary kriging, where Gaussian processes are assumed to have constant mean, carry over to the more realistic case of universal kriging, where \( Z \) is a Gaussian process with mean

\[
EZ(x) = \sum_{i=0}^{p} \beta_i f_i(x) = \beta^T f(x)
\]

and covariance function \( C \), where \( f_i \) are specified functions and \( \beta_i \) are regression coefficients. Typically, \( f_0 \equiv 1 \). In the case of universal kriging, the \((n+1)\)-dimensional Gaussian probability distributions \( P_n \) and \( \hat{P}_n \) of \((Z(x_0), Z(x_1), \ldots, Z(x_n))\) with mean vector \((\beta^T f(x_0), \ldots, \beta^T f(x_n))\) and covariance matrices \( \Sigma_n \) and \( \hat{\Sigma}_n \) have to be contiguous almost surely. Since the mean vectors are the same for \( P_n \) and \( \hat{P}_n \), there is no difference in that respect between ordinary kriging and universal kriging. The presence of the nuisance parameter \( \beta \) may effect estimation of the (parameters of the) covariance function. However, typically this will not effect the rate of convergence of the estimated covariance function and hence will also not effect contiguity of \( \{\hat{P}_n\} \) with respect to \( \{P_n\} \). Section 3.4.3 of Cressie (1991) discusses estimation of the covariance function in the presence of the nuisance parameter \( \beta \).

It is possible to include Gaussian measurement error into the model. Suppose we do not observe \( Z(x_1), \ldots, Z(x_n) \) exactly but instead we observe \( Z_i = Z(x_i) + \varepsilon_i \), where \( \varepsilon_1, \ldots, \varepsilon_n \) are i.i.d. \( \mathcal{N}(0, \tau^2) \) random variables. This can be incorporated into the model by adding a term \( \tau^2 \mathbf{1}_{\{t=0\}} \) to the covariance function \( C(t) \) and a term \( \hat{\tau}_n^2 \mathbf{1}_{\{t=0\}} \) to the estimated covariance function \( \hat{C}_n(t) \), where \( \hat{\tau}_n^2 \) is an estimator of \( \tau^2 \). With those adaptations, the main result in Section 2 goes through unchanged.

2. Asymptotic efficiency of the estimating kriging predictor

Let \( x_0, x_1, x_2, \ldots \) be an infinite sequence of distinct points in a (not necessarily bounded) subset \( D \) of \( \mathbb{R}^d \). Let \( \{Z(x) : x \in \mathbb{R}^d\} \) be a stationary
Gaussian process with mean \( EZ(x) \equiv 0 \), covariance function

\[
C(t) = \text{covar}(Z(x + t), Z(x)),
\]

and probability law \( \mathbb{P} \). We think of \( C \) as the true, but typically unknown, underlying covariance function of the process. Define \( Z_i = Z(x_i), i = 1, \ldots, n \).

We observe \( Z_1, \ldots, Z_n \) and we wish to predict \( Z_0 = Z(x_0) \) on the basis of these observations. Let \( \Sigma_n \) be the \((n + 1) \times (n + 1)\) covariance matrix of \( Z_0, Z_1, \ldots, Z_n \), where for convenience we let indices run from 0 to \( n \), i.e.

\[
(2.1) \quad \Sigma_{n,ij} = \text{covar}(Z(x_i), Z(x_j)) = C(x_i - x_j), \quad i, j = 0, 1, \ldots, n.
\]

We also define the \( n \times n \) submatrix \( \Omega_n \), the \( n \)-vector \( \omega_n \) and scalar \( \sigma^2 \) by

\[
\Omega_{n,ij} = \Sigma_{n,ij}, \quad i, j = 1, \ldots, n,
\]

\[
\omega_{n,i} = \Sigma_{n,0i}, \quad i = 1, \ldots, n,
\]

\[
\sigma^2 = \Sigma_{n,ii} = C(0), \quad i = 0, \ldots, n.
\]

Then for \( \alpha_n = (\alpha_{n1}, \ldots, \alpha_{nn})^T \),

\[
(2.2) \quad \alpha_n = \Omega_n^{-1} \left( \omega_n + \frac{1 - 1^T \Omega_n^{-1} \omega_n}{1^T \Omega_n^{-1} 1} \right)
\]

defines an \( n \)-vector which clearly satisfies \( 1^T \alpha_n = \sum_{i=1}^n \alpha_{ni} = 1 \). Here \( 1 \) denotes an \( n \)-vector consisting of 1’s and \( a^T \) denotes the transpose of a vector or matrix \( a \). Define the linear predictor

\[
(2.3) \quad Z_n(x_0) = \sum_{i=1}^n \alpha_{ni} Z(x_i)
\]

and its error

\[
(2.4) \quad e_n(x_0) = Z_n(x_0) - Z(x_0).
\]

The weights \( \alpha_{ni} \) defined by equation (2.2) are such that \( Z_n(x_0) \) is unbiased and that \( \text{var}_C(e_n(x_0)) \) is minimised among all weights \( \alpha_{ni} \) with \( \sum_{i=1}^n \alpha_{ni} = \)
1. We call $Z_n(x_0)$ the theoretical kriging predictor and its mean squared error

$\text{var}_C(e_n(x_0)) = \sigma^2 - \omega^T_n \Omega_n^{-1} \omega_n + \frac{(1^T \Omega_n^{-1} \omega_n - 1)^2}{1^T \Omega_n^{-1} 1}$

the theoretical kriging prediction error.

Having observed $Z_1, \ldots, Z_n$, let $\hat{C}_n(t)$ be an estimator of $C(t)$ based on $Z_1, \ldots, Z_n$. Analagous to (2.1)–(2.2), define $\hat{\Sigma}_n$, $\hat{\Omega}_n$, $\hat{\omega}_n$, $\hat{\sigma}_n^2$ and $\hat{\alpha}_n$ by

(2.6) \quad \hat{\Sigma}_{n,ij} = \hat{C}_n(x_i - x_j), \quad i, j = 0, 1, \ldots, n ,

(2.7) \quad \hat{\Omega}_{n,ij} = \hat{\Sigma}_{n,ij}, \quad i, j = 1, \ldots, n ,

(2.8) \quad \hat{\omega}_{n,i} = \hat{\Sigma}_{n,0i}, \quad i = 1, \ldots, n ,

(2.9) \quad \hat{\sigma}_n^2 = \hat{\Sigma}_{n,ii} = \hat{C}_n(0), \quad i = 0, \ldots, n ,

and

(2.10) \quad \hat{\alpha}_n = \Omega_n^{-1} \left( \hat{\omega}_n + 1 - \frac{1^T \Omega_n^{-1} \hat{\omega}_n}{1^T \Omega_n^{-1} 1} \right).

The resulting linear predictor

(2.11) \quad \hat{Z}_n(x_0) = \sum_{i=1}^{n} \hat{\alpha}_{n,i} Z(x_i)

is called the estimating kriging predictor. Clearly, this is no longer the optimal unbiased linear predictor of $Z(x_0)$. In fact, it does not necessarily enjoy any of those properties (optimal, unbiased, linear), the latter two failing because $\hat{\alpha}_{n,i}$ now depends on $Z_1, \ldots, Z_n$. It has to be noted though, that the estimating kriging predictor is in fact often unbiased (Christensen 1991). Let

(2.12) \quad \hat{e}_n(x_0) = \hat{Z}_n(x_0) - Z(x_0).

Its variance $\text{var}_C(\hat{e}_n(x_0))$ is the prediction mean squared error of the estimating kriging predictor $\hat{Z}_n(x_0)$ and is called the estimating kriging prediction error.
To state our result we need to define contiguity first. For every \( n \), let \((X_n, A_n)\) be a measurable space and let \( \{Q_n\} \) and \( \{Q'_n\} \) be two sequences of probability measures on \((X_n, A_n)\).

**Definition 2.1.** The sequence \( \{Q'_n\} \) is *contiguous* with respect to \( \{Q_n\} \) if for every \( A_n \in A_n \), \( Q_n(A_n) \to 0 \) implies \( Q'_n(A_n) \to 0 \).

For more information on contiguity, see Roussas (1972) or Prakasa Rao (1987).

Let \( P_n \) and \( \hat{P}_n \) to be the \((n+1)\)-dimensional Gaussian distributions with mean zero and covariance matrices \( \Sigma_n \) and \( \hat{\Sigma}_n \) respectively. We shall call \( \hat{Z}_n(x_0) \) asymptotically efficient with respect to \( Z_n(x_0) \) if

\[
\lim_{n \to \infty} \frac{E_C(\hat{Z}_n(x_0) - Z(x_0))^2}{E_C(Z_n(x_0) - Z(x_0))^2} = 1.
\]

(2.13)

Thus, when (2.13) is fulfilled, if \( C \) is the true underlying covariance function, the estimating kriging predictor \( \hat{Z}_n(x_0) \) based on the estimated \( \hat{C}_n \) performs asymptotically equally well as the theoretical kriging predictor \( Z_n(x_0) \) based on the correct covariance function \( C \). Clearly, the definition of asymptotic efficiency in (2.13) depends on the sampling locations \( x_1, x_2, \ldots \). If (2.13) is true for all limit points \( x_0 \) of the sampling locations, then it becomes a property of the covariance function \( C \) and \( \hat{C}_n \) only, and we shall call \( \hat{C}_n \) asymptotically efficient with respect to \( C \).

We are now ready to state the result.

**Theorem 2.1.** If

\[
\text{var}_C(e_n(x_0)) \to 0, \quad \text{as } n \to \infty,
\]

and \( \{\hat{P}_n\} \) and \( \{P_n\} \) are contiguous, \( \mathbb{P} \)-almost surely, then \( \hat{Z}_n(x_0) \) is asymptotically efficient with respect to \( Z_n(x_0) \) as in (2.13).

**Proof.** We shall start by proving (2.13) for a deterministic sequence of alternative covariance functions \( \hat{C}_n \) such that \( \{\hat{P}_n\} \) and \( \{P_n\} \) are contiguous.
Later the requirement that $\hat{C}_n$ be deterministic shall be removed. We follow the proof of Theorem 1 of Stein (1988) quite closely. In the proof we shall use the notation $Z(x)$ to denote a mean zero Gaussian random field on a subset $D$ of $\mathbb{R}^d$. The underlying covariance function is either $C(t)$ or $\hat{C}_n(t)$. It will be clear from the context which is the underlying covariance function; in particular, in calculating (co)variances we shall use the name of the covariance function as a subscript.

Since $Z_n(x_0)$ is optimal under $C$, we must have
\[
\frac{\text{var}_C(e_n(x_0))}{\text{var}_C(\hat{e}_n(x_0))} \leq 1.
\]
Following Stein (1988), we write
\[
\frac{\text{var}_C(e_n(x_0))}{\text{var}_C(\hat{e}_n(x_0))} = \frac{\text{var}_C(e_n(x_0))}{\text{var}_{\hat{C}_n}(e_n(x_0))} \cdot \frac{\text{var}_{\hat{C}_n}(e_n(x_0))}{\text{var}_C(\hat{e}_n(x_0))} \cdot \frac{\text{var}_{\hat{C}_n}(\hat{e}_n(x_0))}{\text{var}_C(\hat{e}_n(x_0))}.
\]
Since $\hat{Z}_n(x_0)$ is optimal under $\hat{C}_n$, we have
\[
(2.15) \quad \frac{\text{var}_{\hat{C}_n}(e_n(x_0))}{\text{var}_{\hat{C}_n}(\hat{e}_n(x_0))} \geq 1.
\]
Hence it suffices to show that
\[
(2.16) \quad \liminf_{n \to \infty} \frac{\text{var}_C(e_n(x_0))}{\text{var}_{\hat{C}_n}(e_n(x_0))} \geq 1,
\]
and
\[
(2.17) \quad \liminf_{n \to \infty} \frac{\text{var}_{\hat{C}_n}(\hat{e}_n(x_0))}{\text{var}_C(\hat{e}_n(x_0))} \geq 1.
\]
Define
\[
Y_n = \frac{e_n(x_0)}{(\text{var}_C(e_n(x_0)))^{1/2}}, \quad \hat{Y}_n = \frac{\hat{e}_n(x_0)}{(\text{var}_{\hat{C}_n}(\hat{e}_n(x_0)))^{1/2}},
\]
so that both $E CY_n = E \hat{C}_n \hat{Y}_n = 0$ and $E C Y_n^2 = E \hat{C}_n \hat{Y}_n^2 = 1$. The appropriate lemma of Stein (1988) now reads
Lemma 2.2. Any subsequence $n_1, n_2, \ldots$ contains a further subsequence $n_{k_1}, n_{k_2}, \ldots$ such that, with $\tilde{Y}_m = Y_{n_{k_m}}$ and $\tilde{P}_m = P_{n_{k_m}}$, we have for every $\varepsilon > 0$

\begin{align}
(2.18) \quad & \tilde{P}_M \left( M^{-1} \sum_{m=1}^{M} \tilde{Y}_m^2 - 1 \right) > \varepsilon \to 0, \text{ as } M \to \infty.
\end{align}

The proof of Lemma 2.2 goes through unchanged, since it uses only properties of normal random variables and optimality of kriging predictors, which remain true under $\hat{C}$ and $\hat{C}_n$.

For reasons that will become clear later, we proceed by proving a slightly stronger statement than (2.16), namely

\begin{align}
(2.19) \quad & \lim_{n \to \infty} \frac{\text{var}_C(e_n(x_0))}{\text{var}_{\hat{C}_n}(e_n(x_0))} = 1.
\end{align}

Supposing that (2.19) is not true, there exists a subsequence $n_1, n_2, \ldots$ satisfying

\begin{align}
(2.20) \quad & \lim_{k \to \infty} \frac{\text{var}_C(e_{n_k}(x_0))}{\text{var}_{\hat{C}_{n_k}}(e_{n_k}(x_0))} = \lim_{k \to \infty} \frac{\text{var}_C(Y_{n_k})}{\text{var}_{\hat{C}_{n_k}}(Y_{n_k})} = \lim_{k \to \infty} \frac{1}{\tau_{n_k}^2} = c \neq 1,
\end{align}

where $\tau_n^2 = \text{var}_{\hat{C}_n}(Y_n)$. Note that $c > 0$, since otherwise, with $\mu_n = E_{\hat{C}_n}Y_n$, we would have, $Y_n$ being normal,

\begin{align}
\hat{P}_{n_k} \left( |Y_{n_k} - \mu_{n_k}| > \frac{\tau_{n_k}}{2} \right) \to 0, \quad \hat{P}_{n_k} \left( |Y_{n_k} - \mu_{n_k}| > \frac{\tau_{n_k}}{2} \right) \to 1,
\end{align}

which is in contradiction with the contiguity of $\{P_n\}$ and $\{\hat{P}_n\}$. So let us suppose that as $k \to \infty$,

\begin{align}
(2.21) \quad & \text{var}_{\hat{C}_{n_k}}(Y_{n_k}) \to c^{-1} < \infty,
\end{align}

Pick a further subsequence such that (2.18) holds. For that subsequence we have,

\begin{align}
(2.22) \quad & \lim_{M \to \infty} E_{\hat{C}_M} \left( M^{-1} \sum_{m=1}^{M} \tilde{Y}_m^2 \right) = c^{-1}.
\end{align}
By the contiguity of \( \{P_n\} \) and \( \{\hat{P}_n\} \) we have
\[
\hat{P}_M \left( \left| \sum_{m=1}^{M} \tilde{Y}_m^2 - 1 \right| > \varepsilon \right) \to 0, \quad \text{as } n \to \infty,
\]
for all \( \varepsilon > 0 \). Also, since \( Z(x) \) is Gaussian, using (2.21), we have, as \( M \to \infty \),
\[
\text{var} \hat{C}_M \left( \sum_{m=1}^{M} \tilde{Y}_m^2 \right) = 2M^{-2} \sum_{l=1}^{M} \sum_{m=1}^{M} \text{covar} \hat{C}_M (\tilde{Y}_l, \tilde{Y}_m)^2 \leq 2M^{-2} \sum_{l=1}^{M} \sum_{m=1}^{M} \text{var} \hat{C}_M (\tilde{Y}_l) \cdot \text{var} \hat{C}_M (\tilde{Y}_m) \to 2c^{-2}.
\]
Applying Theorem 4.5.2 in Chung (1974) to (2.23), we obtain
\[
\lim_{M \to \infty} E \hat{C}_M \left( \sum_{m=1}^{M} \tilde{Y}_m^2 \right) = 1,
\]
which is in contradiction with (2.22). Thus, we have established (2.19) and a fortiori (2.16). It remains to show (2.17). Now, using the proof above on \( \hat{Y}_n \), (2.17) will follow from (2.16) only if the analogue of (2.14) holds for \( \hat{C}_n \) and \( \hat{e}_n(x_0) \) as well (this is a small gap in the proof of Stein (1988)!), i.e. we want
\[
\text{var} \hat{C}_n (\hat{e}_n(x_0)) \to 0 \quad \text{as } n \to \infty,
\]
(2.24)

Note however that
\[
\frac{\text{var} \hat{C}_n (\hat{e}_n(x_0))}{\text{var} C(\hat{e}_n(x_0))} = \frac{\text{var} \hat{C}_n (\hat{e}_n(x_0))}{\text{var} \hat{C}_n (e_n(x_0))} \cdot \frac{\text{var} \hat{C}_n (e_n(x_0))}{\text{var} C(e_n(x_0))}.
\]
(2.25)

The first term of the right hand side of (2.25) is less than or equal to 1 by (2.15), the latter tends to 1 by (2.19). Hence
\[
\limsup_{n \to \infty} \frac{\text{var} \hat{C}_n (\hat{e}_n(x_0))}{\text{var} C(\hat{e}_n(x_0))} \leq 1,
\]
which together with (2.14) establishes (2.24). Hence, Lemma 2.2 can be applied to \( Y_n \) under \( \hat{P}_n \) and the contradiction argument following that, to prove (2.17) and (2.14) for a deterministic sequence of alternative covariance functions \( \hat{C}_n \) such that \( \{\hat{P}_n\} \) and \( \{P_n\} \) are contiguous.
To finish the proof, we note that for \( \hat{C}_n \) random such that \( \{ \hat{P}_n \} \) and \( \{ P_n \} \) are contiguous \( \mathbb{P} \)-almost surely, the conclusion (2.14) remains valid since a \( \mathbb{P} \)-null exceptional set where \( \{ \hat{P}_n \} \) and \( \{ P_n \} \) are possibly non-contiguous does not contribute to the integrals in (2.13).

3. Conditions for contiguity

Recall the definition of contiguity given in Definition 2.1 and consider the special case where

\[
Q_n = \prod_{i=1}^{n} Q_{ni}, \quad Q'_n = \prod_{i=1}^{n} Q'_{ni}
\]

are product measures on a product space \( (X_n, A_n) = (\prod_{i=1}^{n} X_{ni}, \prod_{i=1}^{n} A_{ni}) \) with marginals \( Q_{ni} \) and \( Q'_{ni} \) on \( (X_{ni}, A_{ni}) \). Let \( q_{ni} \) and \( q'_{ni} \) be densities of \( Q_{ni} \) and \( Q'_{ni} \) with respect to \( \sigma \)-finite measures \( \mu_{ni} \) on \( (X_{ni}, A_{ni}) \).

**Definition 3.1.** The Hellinger distance between \( Q_{ni} \) and \( Q'_{ni} \) is defined as

\[
H^2(Q_{ni}, Q'_{ni}) = \int \left( q_{ni}^{1/2} - q'_{ni}^{1/2} \right)^2 d\mu_{ni}.
\]

The following relation between contiguity of \( \{ Q_n \} \) and \( \{ Q'_n \} \) has been proved in Oosterhoff & Van Zwet (1979) (see also Prakasa Rao 1987).

**Lemma 3.1.** The sequence \( \{ Q'_n \} \) is contiguous with respect to \( \{ Q_n \} \) if and only if

\[
\limsup_{n \to \infty} \sum_{i=1}^{n} H^2(Q_{ni}, Q'_{ni}) < \infty
\]

and

\[
\lim_{n \to \infty} \sum_{i=1}^{n} \int_{\{x: q'_{ni}(x) \geq c_n q_{ni}(x)\}} q'_{ni}(x) d\mu_{ni}(x) = 0 \quad \text{if } c_n \to \infty.
\]

Supposing that \( P_n \) and \( \hat{P}_n \) are the distributions of \( (n + 1) \)-dimensional Gaussian mean zero vectors with covariance matrices \( \Sigma_n \) and \( \hat{\Sigma}_n \) respectively, the question remains what conditions on \( \Sigma \) and \( \hat{\Sigma}_n \) are needed to
guarantee contiguity of \( \{ \hat{P}_n \} \) with respect to \( \{ P_n \} \). Let us denote the difference between the covariance matrices by
\[
\Delta_n = \hat{\Sigma}_n - \Sigma_n .
\]

**Lemma 3.2.** The sequence \( \{ \hat{P}_n \} \) is contiguous with respect to \( \{ P_n \} \) if and only if there exist \( 0 < K_1 \leq K_2 < \infty \) such that
\[
\limsup_{n \to \infty} \sum_{i=0}^{n} \lambda_i^2 \leq K_2 ,
\]
and
\[
\liminf_{n \to \infty} \inf_{0 \leq i \leq n} \lambda_i \geq -1 + K_1 ,
\]
where \( \lambda_0, \ldots, \lambda_n \) are the eigenvalues of \( \Sigma_n^{-1} \Delta_n \).

**Proof.** By Rao (1965, p. 42, (iv, c)), there exists a nonsingular \((n + 1) \times (n + 1)\)-matrix \( B \) such that
\[
B^T \Sigma_n B = I , \quad \text{and} \quad B^T \hat{\Sigma}_n B = \Lambda^* ,
\]
where \( \Lambda^* \) is diagonal with elements \( \lambda_i^* \) as the eigenvalues of \( \Sigma_n^{-1} \hat{\Sigma}_n = I + \Sigma_n^{-1} \Delta_n \).

It is clear from the definition of contiguity that contiguity is preserved under 1-1 transformations. If \( N_{\sigma^2} \) and \( N_{\tau^2} \) denote normal distributions with mean zero and variance \( \sigma^2 \) and \( \tau^2 \) respectively, it is straightforward to see that
\[
\frac{1}{2} H^2(N_{\sigma^2}, N_{\tau^2}) = 1 - \sqrt{\frac{2\sigma \tau}{\sigma^2 + \tau^2}} = \frac{(\sigma - \tau)^2}{\sigma^2 + \tau^2} \left( 1 + \sqrt{\frac{2\sigma \tau}{\sigma^2 + \tau^2}} \right)^{-1} .
\]

Application of Lemma 3.1 then shows that \( \{ \hat{P}_n \} \) is contiguous with respect to \( \{ P_n \} \) if and only if
\[
\limsup_{n \to \infty} \sum_{i=0}^{n} (\lambda_i^* - 1)^2 < \infty ,
\]
and
\[
\liminf_{n \to \infty} \inf_{0 \leq i \leq n} \lambda_i^* > 0 .
\]
Now let $\lambda_i$ be an eigenvalue of $\Sigma^{-1}\Delta$ with corresponding eigenvector $x_i$. Then

$$\begin{equation}
(I + \Sigma^{-1}\Delta_n)x_i = (1 + \lambda_i)x_i,
\end{equation}$$

so for every eigenvalue $\lambda_i^*$ of $\Sigma_n^{-1}\hat{\Sigma}_n$ there exists an eigenvalue $\lambda_i = \lambda_i^*$ of $\Sigma_n^{-1}\Delta_n$ with common eigenvector $x_i$. Replacing $\lambda_i^* - 1$ by $\lambda_i$ in (3.9) and (3.10) proves the lemma. We note that Ibragimov & Rozanov (1978, p. 70–77) also contains the essential elements of a proof of this lemma.

**Remark 3.1.** The sum of the squares of the eigenvalues of $\Sigma_n^{-1}\Delta_n$ can be calculated by using the trace of the square of $\Sigma_n^{-1}\Delta_n$:

$$\begin{equation}
\sum_{i=1}^{n} \lambda_i^2 = \text{trace}((\Sigma_n^{-1}\Delta_n)^2).
\end{equation}$$

Clearly, $\Sigma_n$ and $\hat{\Sigma}_n$ depend not only on the covariance functions $C$ and $\hat{C}_n$ but also on the spatial configuration of the sampling locations. Via conditions (3.6) and (3.7), the same is true for the Gaussian measures $P_n$ and $\hat{P}_n$. Thus, contiguity of $\{\hat{P}_n\}$ with respect to $\{P_n\}$ and hence most likely asymptotic efficiency of $\hat{Z}_n(x_0)$ with respect to $Z_n(x_0)$ will depend on the location of $x_1, x_2, \ldots, x_n$ with respect to $x_0$. In checking contiguity, one would therefore wish to take that into account. On the other hand, conditions (3.6) and (3.7) might be quite difficult to check in a particular application and it is therefore desirable to give more easily verifiable conditions for contiguity, even if they ignore the configuration of the sampling locations. The following lemma gives conditions, independent of the sampling locations, for contiguity of $\{\hat{P}_n\}$ with respect to $\{P_n\}$. For any covariance function $C$ on $D \subset \mathbb{R}^d$, let $f$ denote its spectral density (assuming it exists), i.e.

$$\begin{equation}
C(t) = \int_{\mathbb{R}^d} e^{i\langle t, \nu \rangle} f(\nu) d\nu,
\end{equation}$$
where for \( t \) and \( \nu \) in \( \mathbb{R}^d \), \( < t, \nu > = \sum_{j=1}^{d} t_j \nu_j \). The spectral density can be found from the covariance function by the inverse formula of (3.13)

\[
(3.14) \quad f(\nu) = (2\pi)^{-d} \int_{\mathbb{R}^d} e^{-i < t, \nu >} C(t) dt .
\]

**Lemma 3.3.** Suppose that \( C \) and \( \hat{C}_n \) have spectral measures \( F \) and \( \hat{F}_n \) respectively which are absolutely continuous with respect to \( d \)-dimensional Lebesgue measure with densities \( f \) and \( \hat{f}_n \) respectively. Then \( \{ \hat{P}_n \} \) is contiguous with respect to \( \{ P_n \} \) if

\[
(3.15) \quad \limsup_{n \to \infty} n \sup_{\nu \in \mathbb{R}^d} \left( \frac{\hat{f}_n(\nu) - f(\nu)}{f(\nu)} \right)^2 < \infty
\]

and

\[
(3.16) \quad \liminf_{n \to \infty} \inf_{\nu \in \mathbb{R}^d} \frac{\hat{f}_n(\nu)}{f(\nu)} > 0 .
\]

**Proof.** Let \( \lambda_i \) be an eigenvalue of \( \Sigma_n^{-1} \Delta_n \) with corresponding eigenvector \( y \).

Then

\[
(3.17) \quad \lambda_i \ y^T \Sigma_n y = y^T \Delta_n y ,
\]

and hence

\[
(3.18) \quad |\lambda_i| \leq \sup_y \left| \frac{y^T \Delta_n y}{y^T \Sigma_n y} \right| .
\]

Since

\[
\left| \frac{y^T \Delta_n y}{y^T \Sigma_n y} \right| = \left| \int_{\mathbb{R}^d} \sum_j y_j e^{-ix_j \nu} \frac{2}{f(\nu)} (\hat{f}_n(\nu) - f(\nu)) d\nu \right| \leq \sup_{\nu} \left| \frac{\hat{f}_n(\nu) - f(\nu)}{f(\nu)} \right| ,
\]

we have

\[
\sum_{i=0}^{n} \lambda_i^2 \leq (n + 1) \sup_{\nu} \left( \frac{\hat{f}_n(\nu) - f(\nu)}{f(\nu)} \right)^2 .
\]
Similarly, if $\lambda^*_i$ is an eigenvalue of $\Sigma^{-1}_n \hat{\Sigma}_n^{-1}$, then

$$\lambda^*_i \geq \inf_y \frac{y^T \hat{\Sigma}_n y}{y^T \Sigma_n y} \geq \inf_\nu \frac{\hat{f}_n(\nu)}{f(\nu)}.$$  

The lemma then follows on applying Lemma 3.2.

4. Examples

In this section we shall apply the results of the previous section to a number of examples. The first example has been considered earlier in Stein & Handcock (1989).

**Example 4.1.** Consider equally spaced locations $x_i = \frac{i}{n}$, $i = 0, \ldots, n - 1$ in the unit interval in $\mathbb{R}$ and let, for $|t| \leq 1$,

$$C(t) = 1 - |t|, \quad C_n(t) = C(t) + \beta_n \delta(t), \quad (4.1)$$

where $\beta_n$ is a sequence of bounded real numbers and $\delta(t)$ is a twice continuously differentiable function such that $C_n(t)$ is a permissible covariance function for all $n$. We shall see later that the behaviour of the derivative of $\delta$ at the origin dictates different conditions on $\beta_n$ for $C$ and $C_n$ for $\{\hat{P}_n\}$ and $\{P_n\}$ to be contiguous. If $\Sigma_n$ denotes the covariance matrix of $(Z(x_0), Z(x_1), \ldots, Z(x_{n-1}))$, then clearly $\Sigma_{n,ij} = 1 - \frac{|i-j|}{n}$. The matrix $\Delta_n$ is defined by $\Delta_{n,ij} = \beta_n \delta \left( \frac{|i-j|}{n} \right)$. We use identity (3.12), and study the trace of $(\Sigma^{-1}_n \Delta_n)^2$. Let $D_k$ denote the $k$th diagonal element of $(\Sigma^{-1}_n \Delta_n)^2$ and define

$$\psi(t) = (\delta(t) + \delta(1-t) + \delta'(t))\delta''(t),$$

$$m_n = \frac{1}{n} \sum_{j=2}^{n-1} \psi\left( \frac{j-1}{n} \right) \approx \int_0^1 \psi(t) dt.$$  

Elementary matrix manipulations show that

$$D_1 = D_n \approx \frac{\beta_n^2}{4} \left[ (\delta(0) + \delta(1) + \delta'(0+))^2 + (\delta(0) + \delta(1) + \delta'(1))^2 - m_n \right]$$
and for \( 2 \leq k \leq n - 1 \),

\[
D_k \approx \beta_n^2 \frac{1}{4} \left[ 4(\delta'(0+))^2 - \frac{\psi\left(\frac{k-1}{n}\right) + \psi\left(\frac{n-k}{n}\right)}{n} + \frac{1}{n^2} \sum_{j=2, j \neq k}^{n-1} \left( \delta''\left(\frac{j-k}{n}\right) \right)^2 \right].
\]

If \( \lambda_1, \ldots, \lambda_n \) denote the eigenvalues of \( \Sigma_n^{-1} \Delta_n \), we arrive at

\[
\sum_{i=1}^{n} \lambda_i^2 = \sum_{k=1}^{n} D_k \approx \beta_n^2 \left[ n(\delta'(0+))^2 + \frac{1}{2} (\delta(0) + \delta(1) + \delta'(0+))^2 \right.
\]

\[
+ \frac{1}{2} (\delta(0) + \delta(1) + \delta'(1))^2 - \int_{0}^{1} \psi(t) dt \left. \right].
\]

It is not difficult to see that the contributions of the remainder terms in (4.2) are indeed negligible. Application of Theorem 2.1 and Lemma 3.2 now tells us that the kriging predictor based on \( C_n \) is asymptotically efficient if \( \sum_{i=1}^{n} \lambda_i^2 \) in (4.2) is bounded and (3.7) holds. The analysis of \( \sum_{i=1}^{n} \lambda_i^2 \) in (4.2) exhibits two interesting features. First, if, subject to the permissibility condition, \( \delta'(0+) = 0 \), then we are in a situation where \( C_n \) and \( C \) behave similarly at the origin, in the sense that for every \( n \), \( C'_n(0+) = C'(0+) \).

As a result, for every \( n \) the Gaussian processes determined by \( C \) and \( C_n \) respectively are mutually absolutely continuous (with some exceptions) and Theorem 1 in Stein (1988) asserts that for \( \beta_n = \beta \) finite, the kriging predictor based on \( C_n \) is asymptotically efficient. Our analysis shows that if \( \delta'(0+) = 0 \), \( \sum_{i=1}^{n} \lambda_i^2 \) remains bounded whenever \( \beta_n \) remains bounded and hence the estimating kriging prediction error is asymptotically efficient if also (3.7) holds. Stein & Handcock (1989, Example 3) discuss this example for \( \delta(t) = \frac{1-t^2}{2} \) and \( 0 \leq \beta_n \leq 1 \). This indeed makes \( C_n(t) \) a permissible covariance function, since

\[
C_n(t) = C(t) + \beta_n \frac{1-t^2}{2} = (1 - \beta_n)C(t) + \beta_n C_2(t) ,
\]

where for \( |t| \leq 1 \),

\[
C_2(t) = \frac{1}{2} - |t| + \frac{t^2}{2}.
\]
is a permissible covariance function. This follows because its spectral density
\[ f_2(\nu) = (\pi \nu^3)^{-1}(\nu - \sin(\nu)) \]
is nonnegative. The spectral density of \( C(t) \) is given by
\[ f_1(\nu) = (\pi \nu^2)^{-1}(1 - \cos(\nu)) . \]
Now (3.16) of Lemma 3.3 implies that (3.7) is fulfilled if
\[ \lim_{n \to \infty} \sup \beta_n < 1 , \]
since if \( f(\nu) \equiv f_1(\nu) \) and \( \hat{f}_n(\nu) = f_1(\nu) + \beta_n(f_2(\nu) - f_1(\nu)) \) denote the spectral densities of \( C \) and \( C_n \) respectively, we have
\[ \frac{\hat{f}_n(\nu)}{f(\nu)} \geq 1 + \beta_n \frac{f_2(\nu) - f_1(\nu)}{f_1(\nu)} = 1 + \beta_n \frac{\cos \nu - \sin \nu}{1 - \cos \nu} \geq 1 - \beta_n , \]
the latter inequality because \( \frac{\sin \nu}{\nu} \leq 1 \). Lemma’s 3.2 and 3.3 together with Theorem 2.1 imply that for \( \delta(t) = \frac{1-t^2}{2} \), if (4.3) holds, the estimating kriging predictor is asymptotically efficient with respect to the theoretical kriging predictor. Thus, here our result is in agreement with Example 3 in Stein & Handcock (1989).

For the case \( \delta'(0+) \neq 0 \), Lemma 3.2 gives valuable additional information.

Now for fixed \( n \), unless \( \beta_n = 0 \), the Gaussian processes governed by \( C \) and \( C_n \) are not absolutely continuous, so Theorem 1 of Stein (1988) cannot be applied. It is easy to see that \( \sum_{i=1}^{n} \lambda_i^2 \) remains bounded if \( \beta_n = O\left(\frac{1}{\sqrt{n}}\right) \), so for \( \{\hat{P}_n\} \) to be contiguous with respect to \( \{P_n\} \) we need \( \beta_n \) to be of the order \( O\left(\frac{1}{\sqrt{n}}\right) \).

**Example 4.2. Exponential covariance functions.** Consider a Gaussian process on \( \mathbb{R} \) with covariance function
\[ C_{\theta, \sigma^2}(t) = \sigma^2 e^{-\theta |t|} , \quad \sigma^2, \theta > 0 . \]
Suppose the process is observed at \( x_i = i/a_n, i = 1, \ldots, n - 1 \) and is to be predicted at \( x_0 = 0 \). Here \( a_n \) determines the degree of infilling and increasing domain. In particular, \( a_n = O(n) \) corresponds to infill asymptotics and
$a_n = O(1)$ corresponds to increasing domain asymptotics. The sequence $a_n$ is assumed to be inside the boundaries described above. Let $\theta_n$ and $\sigma^2_n$ be bounded sequences of numbers. Summing up, we assume that there exist constants $0 < K_1 \leq K_2 < \infty$ such that

$$K_1 \leq a_n \leq K_2 n, \quad |\theta_n - \theta| \leq K_2, \quad |\sigma^2_n - \sigma^2| \leq K_2.$$  

(4.5) 

As before, let $P_n$ be the joint distribution of the process at prediction and sampling locations under $C_{\theta, \sigma^2}$ and let $\hat{P}_n$ be the joint distribution of the process at the same locations under $C_{\theta_n, \sigma^2_n}$.

We shall investigate, under various degrees of infilling, what rates are necessary to obtain contiguity of $\{P_n\}$ and $\{\hat{P}_n\}$. In this setup we have

$$\Sigma_{n, i j} = \sigma^2 \rho^{|i - j|}, \quad \rho = \exp(-\theta/a_n),$$  

(4.6) 

the inverse of which is given in Cressie (1991, p. 133). Similarly, define $\tilde{\Sigma}_n$ by substituting $\theta_n$, $\sigma^2_n$ and $\rho_n = \exp(-\theta_n/a_n)$ for $\theta$, $\sigma^2$ and $\rho$ in (4.6). Finally, let

$$c_n = \frac{\sigma^2_n}{\rho_n} \frac{1 - \rho \rho_n}{1 - \rho^2}.$$  

As in Example 4.1, we use (3.12) and study the sum of the diagonal elements $D_k$ of $(\Sigma_n^{-1} \Delta_n)^2$. Straightforward calculations yield

$$\sum_{i=1}^{n} \lambda^2_i = \sum_{k=1}^{n} D_k = S_1 + S_2 + S_3,$$

where

$$S_1 = (2c_n - 1)^2 + (n - 2) \left( c_n \frac{1 - 2 \rho \rho_n + \rho^2}{1 - \rho \rho_n} - 1 \right)^2 + \frac{2c_n^2 (\rho_n - \rho)^2}{(1 - \rho \rho_n)^2} \rho_n^{2(n-1)},$$

$$S_2 = 4 \rho_n c_n^2 (\rho_n - \rho)^2 \frac{1 - \rho_n^{2(n-2)}}{1 - \rho_n^2},$$

$$S_3 = \frac{2c_n^2 (\rho_n - \rho)^2}{1 - \rho_n^2} \left[ (n - 2) - \frac{1 - \rho_n^{2(n-2)}}{1 - \rho_n^2} \right].$$
The order of magnitude of these terms can be analysed using (4.5) and noting that

\[ c_n = \mathcal{O}(1), \; \rho_n - \rho = \mathcal{O}(a_n^{-1}(\theta_n - \theta)), \; 1 - \rho_n^2 = \mathcal{O}(a_n^{-1}), \; 1 - \rho_n^{2n} = \mathcal{O}(1), \]

which yields

\[ S_1 = \mathcal{O}\left(n\left(\frac{\sigma_n^2\theta_n}{\sigma^2\theta} - 1\right)^2\right), \; S_2 = \mathcal{O}((\theta_n - \theta)^2), \; S_3 = \mathcal{O}\left(\frac{n}{a_n}(\theta_n - \theta)^2\right). \]

Under infill asymptotics (i.e. \( a_n = \mathcal{O}(n) \)), it is well known (Ying 1991) that \( \theta \) and \( \sigma^2 \) cannot be estimated consistently. In fact, \( \theta \) and \( \sigma^2 \) are not identifiable from observing the whole path of the processes, because for \( \hat{\theta}\hat{\sigma}^2 = \theta\sigma^2 \), the Gaussian processes with mean zero and covariance functions \( C_{\theta,\sigma^2} \) and \( C_{\hat{\theta},\hat{\sigma}^2} \) are mutually absolutely continuous. Ying (1991) shows that the maximum likelihood estimators \( \hat{\theta}_n \) and \( \hat{\sigma}_n^2 \) of \( \theta \) and \( \sigma^2 \) are such that \( \sqrt{n}(\hat{\theta}_n - \theta) \) and \( \sqrt{n}(\hat{\sigma}_n^2 - \sigma^2) \) are bounded a.s. Thus, for the maximum likelihood estimators, \( \sum_{i=1}^{n} \lambda_i^2 \) is bounded a.s.

It is instructive to see how far Lemma 3.3 can bring us in checking the conditions of Lemma 3.2. Let \( f \) and \( \hat{f}_n \) denote the spectral density corresponding to \( C_{\theta,\sigma^2} \) and \( C_{\theta_n,\sigma_n^2} \) respectively. Then (Priestley 1981, p. 236)

\[ f(\nu) = \frac{\sigma^2\theta}{\pi(\theta^2 + \nu^2)}, \; \hat{f}_n(\nu) = \frac{\sigma_n^2\theta_n}{\pi(\theta_n^2 + \nu^2)}. \]

It is easily seen that the supremum of \( \left(\frac{\hat{f}_n(\nu) - f(\nu)}{f(\nu)}\right)^2 \) is attained either at \( \nu = 0 \) or at \( \nu = \infty \), depending on the relative signs of \( \sigma_n^2\theta_n - \sigma^2\theta \) and \( \theta_n - \theta \). Thus, (3.15) is fulfilled if both \( \sqrt{n}(\theta_n - \theta) \) and \( \sqrt{n}(\sigma_n^2 - \sigma^2) \) are bounded. This corresponds to the worst case scenario of increasing domain asymptotics above, where \( a_n = \mathcal{O}(1) \). We cannot expect a condition which guarantees (3.6) for all configurations of sampling locations to give a better result than this.
Lemma 3.3 can also help us to check (3.7) of Lemma 3.2. It is easy to see that (3.16) is fulfilled if $\sigma_n^2$ and $\theta_n$ are bounded away from 0 and $\infty$. Thus, a combination of Lemma 3.2 and Lemma 3.3 shows that $\{P_n\}$ and $\{\hat{P}_n\}$ are contiguous under (4.5) if

$$
\theta_n - \theta = O\left(\left(\frac{a_n}{n}\right)^{-1/2}\right), \quad \sigma_n^2 \theta_n - \sigma^2 \theta = O(n^{-1/2}).
$$

(4.7)

Under infill asymptotics, these rates are achieved by the maximum likelihood estimators, as proved by Ying (1991). Under increasing domain asymptotics restricted maximum likelihood estimators exist achieving (4.7) (Cressie & Lahiri 1996). We conjecture that also for $a_n \to \infty$ but $a_n = O(n)$ these rates can be achieved.

The exponential covariance function model in $\mathbb{R}$, given by (4.4) can be extended to more dimensions in two ways. One is retaining isotropy, leading to

$$
C_{\theta, \sigma^2}(t) = \sigma^2 \exp(-\theta ||t||), \quad t \in \mathbb{R}^d,
$$

(4.8)

where $||t|| = (\sum_{j=1}^d t_j^2)^{1/2}$ is the Euclidean length of the vector $t$. In this model the identifiability problem remains for $d \leq 3$, i.e. $\theta$ and $\sigma^2$ are not identifiable and only the product $\theta \sigma^2$ can be estimated at $\sqrt{n}$-rate.

A second extension,

$$
C_{\theta_1, \ldots, \theta_d, \sigma^2}(t) = \sigma^2 \exp\left(-\sum_{j=1}^d \theta_j |t_j|\right),
$$

(4.9)

is mathematically more tractable. It has generally been motivated by applications other than those involving spatial data, such as the modelling of computer experiments. In such a context, distance between two points may be defined in terms of the number of nodes between them on some grid, leading naturally to consideration of this form of covariance function. In Ying (1993) it is shown that $\theta_1, \ldots, \theta_n$ and $\sigma^2$ are identifiable and asymptotic normality of the maximum likelihood estimators $\hat{\theta}_1, \ldots, \hat{\theta}_d$ and $\hat{\sigma}^2_n$ is proved.
The same model was considered by van der Vaart (1996), who proved local asymptotic normality for this model under a two-dimensional regularly spaced grid. It is well known that local asymptotic normality implies contiguity (Bickel et al. 1993, p. 16–17), so the local asymptotic normality proved by van der Vaart (1996) guarantees that the maximum likelihood estimators are such that \( \{ P_n \} \) and \( \{ \hat{P}_n \} \) are contiguous almost surely.

5. Estimation of prediction error

Estimation of the kriging error in the case where the underlying covariance function \( C \) is known is straightforward; if \( C \) is known then formula (2.5) gives the result. An obvious thing to do when \( C \) is unknown is to use (2.5), replacing unknown quantities by their estimated counterparts. Using the notation of (2.6)–(2.9), we then estimate \( \text{var}_C(\hat{e}_n(x_0)) \) by

\[
\text{var}_C(\hat{e}_n(x_0)) = \sigma_n^2 - \omega_n^T \hat{\Omega}_n^{-1} \omega_n + \frac{(1^T \hat{\Omega}_n^{-1} \omega_n - 1)^2}{1^T \hat{\Omega}_n^{-1} 1}.
\]

Computation of (5.1) requires hardly any additional effort, since most of the quantities are needed to compute \( \hat{\alpha}_n \) in the first place. It can be shown as a byproduct of Theorem 2.1 that \( \text{var}_C(\hat{e}_n(x_0)) \) is a consistent estimator of \( \text{var}_C(\hat{e}_n(x_0)) \).

\textbf{Lemma 5.1.} \textit{Under the conditions of Theorem 2.1,}

\[
\frac{\text{var}_C(\hat{e}_n(x_0))}{\text{var}_C(\hat{e}_n(x_0))} \to 1, \quad \mathbb{P} - a.s.
\]

\textit{Proof.} The result follows immediately from (2.17).
