# Embedding the Big Bang Cosmological Model into a Bayesian Hierarchical Model 

David A. van Dyk

Statistics Section, Imperial College London
Joint work with Roberto Trotta, Xiyun Jiao, and Hikmatali Shariff

Joint Statistical Meetings<br>August 2014

## Themes

## The Accelerating Expansion of the Universe

- The role of Dark Energy are Dark Matter in the evolutionary history of the Universe remain mysterious.
- Charting the expansion history is key to testing physical theories for Dark Matter and Dark Energy.
- To do this, we embed cosmological models into a Bayesian hierarchical model.
- Principled handling of data and model complexity.
- Gain better astronomical measurements along the way.

## Outline

(1) Measuring the Expansion of the Universe
(2) A Hierarchical Statistical Model
(3) Shrinkage Estimates of Absolute Magnitudes

Imperial College

## The Expanding Universe

## Redshift

http://www.noao.edu/image_gallery/html/im0566.html
For "nearby" objects,

$$
z=\text { velocity } / c
$$

velocity $=H_{0}$ distance .

## Hubble's Famous Diagram

Velocity-Distance Relation among Extra-Galactic Nebulae.
Radial velocities, corrected for solar motion, are plotted against distances estimated from involved stars and mean luminosities of nebulae in a cluster. The black discs and full line represent the solution for solar motion using the nebulae individually; the circles and broken line represent the solution comblning the nebulae into groups; the cross represents the mean velocity corresponding to the mean distance of 22 nebulae whose distances could not be estimated individually.
Hubble (1929)

## Distance Modulus in an Expanding Universe

Apparent magnitude - Absolute magnitude = Distance modulus:

$$
m-M=\mu=5 \log _{10}(\text { distance }[\mathrm{Mpc}])+25
$$

Computing absolute magnitudes, relationship between $\mu$ and $z$

- For nearby objects, distance $=z c / H_{0}$.
(Correcting for peculiar/local velocities.)
- For distant objects, involves expansion history of Universe:

$$
\mu=g\left(z, \Omega_{\Lambda}, \Omega_{M}, H_{0}\right)
$$

http://skyserver.sdss.org/dr1/en/astro/universe/universe.asp Imperial College London

## Accelerating Expansion of the Universe

Recall: $m-M=\mu=g\left(z, \Omega_{\Lambda}, \Omega_{M}, H_{0}\right)$

- 2011 Physics Nobel Prize: discovery that expansion rate is increasing.
- Dark Energy is principle theorized explanation of acceleration.
- $\Omega_{\Lambda}$ : density of dark energy
(describes acceleration).
- $\Omega_{M}$ : total matter.

If we observe both $m$ and $M$ we can infer $\mu$ and the cosmological parameters.

## Type la Supernovae as Standardizable Candles

If mass surpasses "Chandrasekhar threshold" of $1.44 M_{\odot} \ldots$

Image Credit: http://hyperphysics.phy-astr.gsu.edu/hbase/astro/snovcn.html
Common "flashpoint" $\rightarrow$ similar absolute magnitudes

$$
M_{i} \sim \mathrm{~N}\left(M_{0}, \sigma_{\mathrm{int}}^{2}\right)
$$

Non-linear Regression: $m_{B i}=g\left(z_{i}, \Omega_{\Lambda}, \Omega_{M}, H_{0}\right)+M_{i}$

## Photometric Light Curves: The Raw Data

We use peak $B$ band magnitudes ${ }_{\text {(apparent magnitud }=}=-2.5 \log _{10}(f(\mathrm{lux}))$

## Predicting Absolute Magnitude

SN1a absolute magnitudes are correlated with characteristics of the explosion / light curve:

- $x_{i}$ : rescale light curve to match mean template
- $c_{i}$ : describes how flux depends on color (spectrum)

Credit: http://hyperphysics.phy-astr.gsu.edu/hbase/astro/snovcn.html

Cite: SALT and SALT II (Guy et al. 2005 and 2007).

## Phillips Corrections

- Recall: $m_{B i}=\mu_{i}+M_{i}$

$$
M_{i} \sim \mathrm{~N}\left(M_{0}, \sigma_{\mathrm{int}}^{2}\right) .
$$

- Regression:

$$
\begin{aligned}
M_{i} & =-\alpha x_{i}+\beta c_{i}+M_{i}^{\epsilon} \\
m_{B i} & =\mu_{i}-\alpha x_{i}+\beta c_{i}+M_{i}^{\epsilon} \\
M_{i}^{\epsilon} & \sim \mathrm{N}\left(M_{0}, \sigma_{\epsilon}^{2}\right) .
\end{aligned}
$$

- $\sigma_{\epsilon}^{2} \leqslant \sigma_{\mathrm{int}}^{2}$
- Including $x_{i}$ and $c_{i}$ reduces variance and increases precision of estimates.

## Low-z calibration sample

## Brighter SNla are slower decliners over time.

## Data

## Two samples:

© An Sloan Digital Sky Survey (2009) sample of 288 SNIa. ${ }^{1}$
(2) A larger JLA sample ${ }^{2}$ of 740 SNIa observed with SDSS, Hubble Space Telescope, SNLS (Canada-France-Hawaii Telescope), and several other telescopes for low z SNla.

[^0]
## Outline

## (1) Measuring the Expansion of the Universe

## (2) A Hierarchical Statistical Model

(3) Shrinkage Estimates of Absolute Magnitudes

## The Baseline Hierarchical Model

Level 1: $c_{i}, x_{i}$, and $m_{B i}$ are observed with error.

$$
\left(\begin{array}{c}
\hat{c}_{i} \\
\hat{x}_{i} \\
\hat{m}_{B i}
\end{array}\right) \sim \mathrm{N}\left\{\left(\begin{array}{c}
c_{i} \\
x_{i} \\
m_{B i}
\end{array}\right), \Sigma_{i}\right\}
$$

with $m_{B i}=\mu_{i}+M_{i}^{\epsilon}-\alpha x_{i}+\beta c_{i}$ and $\mu_{i}=g\left(z_{i}, \Omega_{\Lambda}, \Omega_{M}, H_{0}\right)$

## Level 2:

(1) $c_{i} \sim \mathrm{~N}\left(c_{0}, R_{c}^{2}\right)$
(2) $x_{i} \sim \mathrm{~N}\left(x_{0}, R_{x}^{2}\right)$
(3) $M_{i}^{\epsilon} \sim \mathrm{N}\left(M_{0}, \sigma_{\epsilon}^{2}\right)$

Level 3: Priors on $\alpha, \beta, \Omega_{\Lambda}, \Omega_{M}, H_{0}, c_{0}, R_{c}^{2}, x_{0}, R_{x}^{2}, M_{0}, \sigma_{\epsilon}^{2}$

## Accounting for Systematic/Instrumental Effects

- Systematic errors: differences among telescopes, their components, and observational conditions.
- Total Variance: $\Sigma=\Sigma_{\text {stat }}+\Sigma_{\text {sys }}$
- Blocks: SNLS, HST, SDSS, low z.
- Similar to random effect for telescope.

## Effect on Fitted Cosmological Parameters

Imperial College
London

## Adjusting for Galactic Masses

## Can we further reduce the residual error by adjusting for the mass of the host galaxy?

Comparing $\mathrm{E}\left(M_{i}^{\epsilon} \mid Y\right)$ with estimated mass $\left[\log _{10} M_{\odot}\right]$ of host galaxy.

## Adjusting for Galactic Masses

- The distribution of $M_{i}^{\epsilon}$ appears to depend on host galaxy mass $=w$.
- Only observe $\hat{w}_{i} \sim N\left(w_{i}, \sigma_{w i}\right)$.
- We separate the population:
$M_{i}^{\epsilon} \sim \mathrm{N}\left(M_{01}, \sigma_{\epsilon 1}^{2}\right)$ if galaxy mass $=w_{i}<10$
$M_{i}^{\epsilon} \sim \mathrm{N}\left(M_{02}, \sigma_{\epsilon 2}^{2}\right)$ if galaxy mass $=w_{i} \geqslant 10$.
- This reduces residual variance.
- Better strategies:

$$
\begin{aligned}
& \star M_{i}^{\epsilon} \sim \mathrm{N}\left(M_{0}+\psi w_{i}, \sigma_{\epsilon}^{2}\right) \\
& \star m_{B i}=\mu_{i}+M_{i}^{\epsilon}-\alpha x_{i}+\beta c_{i}+\boldsymbol{\psi} \boldsymbol{w}_{\boldsymbol{i}} \\
& \quad \text { with } w_{i} \sim \mathrm{~N}\left(w_{0}, R_{w}^{2}\right)
\end{aligned}
$$

- Non-linearity / interaction?

## Effect on Fitted Cosmological Parameters

Imperial College London

## Checking the Cosmological Model

We model:

$$
m_{B i}=g\left(z_{i}, \Omega_{\Lambda}, \Omega_{M}, H_{0}\right)-\alpha x_{i}+\beta c_{i}+M_{i}^{\epsilon}
$$

How good of a fit is the cosmological model,

$$
g\left(z_{i}, \Omega_{\Lambda}, \Omega_{M}, H_{0}\right) ?
$$

We can check the model by adding a cubic spline term:

$$
m_{B i}=g\left(z_{i}, \Omega_{\Lambda}, \Omega_{M}, H_{0}\right)+h\left(z_{i}\right)+M_{i}^{\epsilon}-\alpha x_{i}+\beta c_{i}+M_{i}^{\epsilon}
$$

where, $h\left(z_{i}\right)$ is cubic spline term with $K$ knots.

## Checking the Cosmological Model

Fitted cubic spline, $h(z)$, and its errors:

Cubic Spline Curve Fitting ( $K=9$ )

Can use similar methods to compare with competing cosmological models.

## Statistical Computation

```
MH within Gibbs:
1: p( }\mu,X|\Omega,\beta,T
2: \mathcal{M }(\Omega|\mu,X,\beta,T)
3: p(\beta|\mu,X,\Omega,T)
4: p(T| \mu,X,\Omega,\beta)
```

Decondition:
1: $p(\mu, X \mid \Omega, \beta, T)$
2: $\mathcal{M}(\Omega, \mu, X \mid \beta, T)$
3: $\mathcal{M}(\beta, \mu, X \mid \Omega, T)$
4: $p(T \mid \mu, X, \Omega, \beta)$

Permute:
1: $\mathcal{M}(\Omega, \mu, X \mid \beta, T)$
2: $\mathcal{M}(\beta, \mu, X \mid \Omega, T)$
3: $p(\mu, X \mid \Omega, \beta, T)$
4: $p(T \mid \mu, X, \Omega, \beta)$

## Trim:

1: $\mathcal{M}(\Omega \mid \beta, T)$
2: $\mathcal{M}(\beta \mid \Omega, T)$
3: $p(\mu, X \mid \Omega, \beta, T)$
4: $p(T \mid \mu, X, \Omega, \beta)$

## Baseline Hierarchical Model:

- $\quad$ Let $X$ represent the random effects
* $\mu$ and $T$ their means and variances, respectively
* $\beta$ the regression coefficients
$\star \Omega$ the cosmological parameters
- Final sampler is an MH with Partially Collapsed Sampler. ${ }^{3}$
- Steps 1-2 analytically marginalize out $X$ and $\mu$.
- Construct with care: permuting steps may change the stationary distribution of the chain.

## Improved Mixing

MH within Gibbs Sampler

MH within PCG Sampler

## Outline

## (1) Measuring the Expansion of the Universe

## (2) A Hierarchical Statistical Model

(3) Shrinkage Estimates of Absolute Magnitudes

## Shrinkage Estimates in Hierarchical Model

A statistical byproduct: Iow MSE estimates of $M_{i}^{\epsilon}$.

Imperial College
London

## Shrinkage Errors in Hierarchical Model

## Reduced standard errors

Imperial College
London

## Fitting Absolute Magnitudes Without Shrinkage

Under the model, absolute magnitudes are given by

$$
M_{i}^{\epsilon}=m_{B i}-\mu_{i}+\alpha x_{i}-\beta c_{i} \text { with } \mu_{i}=g\left(z_{i}, \Omega_{\Lambda}, \Omega_{M}, H_{0}\right)
$$

Setting
(1) $\alpha, \beta, \Omega_{\Lambda}$, and $\Omega_{M}$ to their minimum $\chi^{2}$ estimates,
(2) $H_{0}=72 \mathrm{~km} / \mathrm{s} / \mathrm{Mpc}$, and
(3) $m_{B i}, x_{i}$, and $c_{i}$ to their observed values
we have

$$
\hat{M}_{i}^{\epsilon}=\hat{m}_{B i}-g\left(\hat{z}_{i}, \hat{\Omega}_{\Lambda}, \hat{\Omega}_{M}, \hat{H}_{0}\right)+\hat{\alpha} \hat{x}_{i}-\hat{\beta} \hat{c}_{i}
$$

with error

$$
\approx \sqrt{\operatorname{Var}\left(\hat{m}_{B i}\right)+\hat{\alpha}^{2} \operatorname{Var}\left(\hat{x}_{i}\right)+\hat{\beta}^{2} \operatorname{Var}\left(\hat{c}_{i}\right)}
$$

## Comparing the Estimates

## Comparing the Estimates of $c_{i}$ and $x_{i}$

Imperial College
London

## Discussion

- Bayesian science-driven hierarchical model provides a platform for honest handling of model \& data complexity.
- Sophisticated computation allows for effecient model fitting.
- Estimation of groups of parameters describing populations of sources not uncommon in astronomy.
- These parameters may or may not be of primary interest.
- Modeling the distribution of object-specific parameters can dramatically reduce both error bars and MSE ...
- ... especially with noisy observations of similar objects.
